Mathematics. - "Note on linear homogeneous sets of points". By Dr. B. P. Haflmeljer. (Communicated by Prof. L. E. J. Brovwer).
(Communicated at the meeting of October 25, 1919).
We shall call a linear set of points $\boldsymbol{x}$ homogeneous in the interval $A B$, if its subset, interior to an arbitrary sub-interval, allows of a uniformly continuous one-one representation on the subset of $\pi$ interior to $A B^{2}$ ).

If the set $\boldsymbol{\pi}$ is everywhere dense in the interval $A B^{2}$ ), each of these representations determines a continuous one-one correspondence between the entire linesegments. As will be shown, we may in this case, assume the correspondences, postulated for a homogeneous set of points, to leave relations of order unaltered.

Let $C D$ be a sub-interval of $A B$ (possibly identical to $A B$ ) and $E$ a point between $C$ and $D$. We consider the following possibilities:

1. For every system of points $C, D$, and $E$ the representation of the interval $C D$ on $C E$ leaves relations of order unaltered.
2. This is not the case.
first case. Suppose a representation of $A B$ on $F H$ has to be effected (order from left to right $A, F, H, B$ ). According to the assumption both $A B$ and $F H$ can be represented on $A H$ with unaltered relations of order, hence $A B$ on $F P H$ in the same way.

Second case. The assumption postulates the existence of an interval $C D$ which can be represented on its sub-interval $C E$ with inverted relations of order. Considering this representation is a continuous one-one correspondence between enture linesegments, it follows from the Drdekind axiom that a point $P$ exists (not necessanily belonging to the set $\pi$ ), which corresponds to itself. This however establishes the possibility of representing the part of $\pi$ interior to $C D$ on itself with inversion of order-relations. It follows that the part of $\pi$ interior to an arbitrary sub-interval of $A B$, possesses this same

[^0]Proceedings Royal Acad. Amsterdam. Vol. XXII.
property, hence all correspondences, postulated for the homogeneous set $\pi$, can be effected in such a way as to leave relations of order unaltered.

We now formulate the following theorem: The linear continuum cannot be composed of two homogeneous sets of points, possessing the same geometric type.

Our demonstration is to be an indirect one. Let the open linesegment $A B$ consist of two sets of points $\pi$ and $\pi^{\prime}$ of the kind mentioned. These sets $\pi$ and $\pi^{\prime}$ possess the same geometric type, that is there exists uniformly continuous one-one correspondence between them. Evidently $\pi$ and $\pi^{\prime}$ are both everywhere dense on $A B$.

To begin with, we assume that this correspondence inverts relations of order. Then $\pi$ can be divided into two subsets $\pi_{1}{ }^{\prime}$ and $\pi_{2}$ such that every point of $\pi_{1}$ is sitnated on the left, and every point of $\pi_{2}$ on the right of the corresponding point of $\pi^{\prime}$. Besides, every point of $\pi_{1}$ lies on the left of every point of $\pi_{3}$. Hence, as $\pi_{1}+\pi_{3}$ is everywhere dense, the Dedwind axiom postulates the existence of a separating point $R$. This point $R$ however can belong to neither $\pi_{1}$ nor $\pi_{2}$. For instance let us assume $R$ to be a point of $\pi_{1}$, then it is situated on the left of the corresponding point of $\pi^{\prime}$ and the continuity of the correspondence makes that this is also the case for all points of $\boldsymbol{x}$ inside a certain finite neighbourhood of $R$, which means a contradiction. Hence $R$ belongs to $\pi^{\prime}$, but this also leads to a contradiction as the fact that $R$ is situated either on the left or on the right of its corresponding point cannot be made to agree with the circumstance that all points of $\boldsymbol{\pi}^{\prime}$ on the left (right) of $R$ are also situated on the left (right) of their corresponding points.

We now come to the second possibility, namely that the correspondence between $\pi$ and $\pi^{\prime}$ leaves relations of order unaltered. We distinguish two cases:

1. The set $\pi$ contains both points situated on the left, and points situated on the right of the corresponding points or $\pi^{\prime}$.
2. All points of $\pi$ lie on the same side of the corresponding points.

First case. Let the point $P_{1}$ of $\boldsymbol{x}$ be situated on the left of 1 ts corresponding point $P_{1}^{\prime}$ and $P_{1}$ on the right of $P_{2}^{\prime}$. The subset of $\pi$ between $P_{1}$ and $P_{2}$, including the endpoints shall be called $\pi_{1}$. Let ${ }_{1} \pi_{1}$ be the subset of $\pi_{1}$ consisting of those points, which, together with all points of $\pi_{1}$ situated more to the left, precede their corres-
ponding points ${ }^{1}$ ), and let $R$ be the last limiting point of ${ }_{2} \pi_{1}$ on the right hand side. Then the assumption that $R$ precedes its corresponding point, as well as the assumption according to which $R$ follows on its corresponding point, leads immediately to a contradiction (we here consider the transformation of the entire segment $A B$ in itself, which is determined by the correspondence between $\pi$ and $\pi^{\prime}$ ). Hence the point $R$ must correspond to itself, but this is out of the question, both if $R$ belongs to $\pi$ or to $\pi$ '.

Second case. All points of $\pi$ lie on the left of the corresponding points. Let the points $P_{1}^{\prime}$ and $P_{2}^{\prime}$ of $\pi^{\prime}$ correspond to $P_{1}$ and $P_{3}$ of $\pi$ respectively and let the order from left to right be $P_{1}, P_{1}^{\prime}, P_{2}, P_{2}^{\prime}$. Of course, such a system of points can always be found.

We choose a point $C$ of $\pi^{\prime}$ on the left of $P_{1}$ and we subject $\pi^{\prime}$ to a uniformly continuous one-one transformation in itself, such that $P_{1}^{\prime}$ passes into $C$ and $P_{2}^{\prime}$ remains in its place. A transformation of this kind can certainly be found as $\pi^{\prime}$ is homogeneous. Let $\pi^{\prime \prime}$ be the transformed set, then a uniformly continuous one-one correspondence exists between $\pi^{\prime \prime}$ and $\pi$, such that $\boldsymbol{\pi}^{\prime \prime}$ contains both points preceding and points coming after the corresponding points, and the reasoning used for the first case can now be applied.

To Prof. L. E J. Brouwer I am indebted for several remarks turned to advantage in the preceding note.

1) "Precede" here stands for "are situated on the left of".

[^0]:    ${ }^{1}$ ) An analogous definition has been given by HaUSDORFF for ordered sets, Grundz. der Mengenlehie p. 173. For linear sets of points Brouwrer has introduced the following more extensive definition: a linear set of points $\pi$ is homogeneous in the interval $A B$ if for each couple $P Q$ of its points interior to $A B$, there exists a continuous one-one transformation of the interval $A B$ in itself, such that $\pi$ passes into itself and the point $P$ into the point $Q$. These Proceedings XX, p. 1194. ${ }^{2}$ ) Which obviously is the case if $\pi$ has any points inside $A B$.
