Mathematics. - " $\Lambda$ simply infinite system of hyperelliptical twisted curves of order five." By Prof. Jan de Vrits.
(Communicated in the meeting of March 25, 1916).
§ 1 . By the equations

$$
\begin{equation*}
\frac{\alpha a^{\prime}{ }_{x}+\beta b_{2}^{2}}{c^{2} x_{x}}=\frac{\alpha a a_{x}^{\prime}+\beta b_{x}^{\prime}}{c_{x}^{\prime}}=\frac{\alpha a a_{2}{ }_{2}+\beta b^{\prime \prime}{ }_{x}}{c^{\prime \prime}{ }_{x}} . \tag{1}
\end{equation*}
$$

a simply infinte system of twisted curves is determined, which are each the partaal, intersection of a cubic and a quadratic surface. For, if, for the sake of brevity, the equations (1) are replaced by

$$
\begin{equation*}
\frac{d^{2} x}{c_{\imath}^{2}}=\frac{d^{\prime} x}{c_{\imath}^{\prime}}=\frac{d^{\prime \prime} r}{c^{\prime \prime}{ }_{x}} \tag{2}
\end{equation*}
$$

It appears that the surfaces $l^{2}{ }_{a} c_{x}=c_{a}^{2} d^{\prime \prime}$ and $c^{\prime}{ }_{3} c^{\prime \prime}{ }_{x}=c^{\prime}{ }_{2} d^{\prime \prime}{ }_{a}$ have in common the straught line $t$, which is represented by $c_{2}^{\prime}=0$, $d^{\prime} x=0$. A plane passing through $t$ intersects the two surfaces moreover along a conic and a straight line; from this it ensues that $t$ is a trisecant of the twisted curve $\imath^{5}$ which is determined by the surfaces mentioned.

As (2) may be replaced by

$$
\begin{equation*}
\frac{d^{3}}{c^{\prime *}{ }_{x}}=\frac{d_{x}^{\prime}+\lambda d_{2}^{\prime \prime}}{c_{2}^{\prime}+\lambda c_{2}^{\prime \prime}}=\frac{d_{2}^{\prime \prime}}{c_{2}^{\prime \prime}} \tag{3}
\end{equation*}
$$

the triseeants of $\rho^{5}$ may be represented by

$$
\begin{equation*}
d_{x}^{\prime}+\lambda \cdot d^{\prime \prime}{ }_{2}=0 \quad, \quad c_{x}^{\prime}+\partial c^{\prime \prime}{ }_{x}=0 . \quad . \quad . \tag{4}
\end{equation*}
$$

They form one of the systems of generatrices on the hyperboloid $d^{\prime} c^{{ }^{\prime}}{ }^{\prime}{ }_{2}=c_{x}^{\prime} l^{\prime \prime}{ }_{a}$; the second system of generatrices consists of bisecants of $v^{5}$.

The trisecants of the curves $\rho^{5}$ determined by (1) are therefore indicated 'by

$$
\begin{equation*}
r a a_{2}^{\prime}+\beta b_{x}^{\prime}+\lambda\left(u a^{\prime \prime}{ }_{x}+\beta b_{x}^{\prime \prime}\right)=0 \quad \cdot \quad c_{x}^{\prime}+\lambda c^{\prime \prime}{ }_{2}=0 \tag{5}
\end{equation*}
$$

They lie on the hyperboloids of the pencil

$$
\begin{equation*}
a\left(a_{x}^{\prime} c^{\prime \prime}{ }_{2}-c^{\prime \prime}{ }_{x} c_{x}^{\prime} x\right)+\beta\left(b_{x}^{\prime} c_{x}^{\prime \prime} x-b^{\prime \prime}{ }_{2} c_{x}^{\prime}\right)=0 \tag{6}
\end{equation*}
$$

The base of this pencil consists of the straight line $c$, represented by $c_{x}^{\prime}=0, c^{\prime \prime}{ }_{z}=0$, and a cubic $\gamma^{\prime}$, of which $c$ is a chord: $\gamma^{3}$ is

$$
\left|\begin{array}{lll}
a_{2}^{\prime \prime} & b_{x}^{\prime} & c_{c}^{\prime}  \tag{7}\\
a_{x}^{\prime \prime} & b_{x}^{\prime \prime} & c_{2}^{\prime \prime}
\end{array}\right|=0
$$

All the trisecants $t$ intersect the straight line $c$ and the basc-curve $\gamma^{n}$; they form therefore the conyruence ( 1,3 ), which has $c$ and $\gamma^{3}$ as directrices.

Through each point of $\gamma^{3}$ passes a plane pencil of trisecants; this appears moreover from (5): the plane pencil in the plane ( $\lambda$ ) has as, vertex the intersection of the planes $a^{\prime}{ }_{2}+2 a^{\prime \prime}{ }_{a}=0, b_{x}+i b^{\prime \prime}{ }_{a}=0$, $c_{2}^{\prime}+2 c_{2}^{\prime \prime}=0$.
§2. As the system (1) may be replaced by the system

$$
\left.\begin{array}{r}
\alpha a^{2} x+\beta b^{2} x+\gamma c_{x}=0 \\
c a^{\prime}{ }_{x}+\beta b_{x}^{\prime}+\gamma c_{x}^{\prime}=0  \tag{8}\\
\alpha a_{x}^{\prime \prime}+\beta b^{\prime \prime} x+\gamma c^{\prime \prime},{ }_{x}=0
\end{array}\right\}
$$

all the curves $o^{5}$ le on the quartic surface $\boldsymbol{\Phi}^{4}$, represented by

$$
\left|\begin{array}{ccc}
a_{x}^{\mathrm{a}} & b_{x}^{2} & c_{x}^{2} \\
a_{x}^{\prime} & b_{x}^{\prime} & c_{x}^{\prime} \\
a_{\perp}^{\prime \prime} & b_{x}^{\prime \prime} & c_{x}^{\prime \prime}
\end{array}\right|=0 \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot(9)-
$$

Through a point of $\Phi^{4}$ passes, in general, one curve $\rho^{\text {' }}$; we shall therefore_call the system ( $\rho^{5}$ ) a pencil.

An arbitrary straght line is therefore cat by four curves $\varrho^{5}$. On $\Phi^{4}$ les also the curve $\gamma^{3}$, any trisecant $t$ intersects $\boldsymbol{\phi}^{4}$ on $\gamma^{3}$ and in the three points, in which it meets the corresponding curve $\varrho^{6}$.

All the $\varrho^{5}$ pass through the points $C_{1}$ and $C_{3}$ indicated by $c_{\imath}{ }^{2}=0$, $c_{a}^{\prime}=0, c^{\prime \prime} x=0$. These points are therefore singular points of ( $\varrho^{5}$ ).

From (1) it appears that the surface $\boldsymbol{\Phi}^{4}$ may be produced by combining the pencil

$$
\begin{equation*}
\alpha\left(a_{\imath} c_{a}^{\prime \prime}-c_{\alpha}^{\prime} a_{x}^{\prime \prime} x\right)+\beta\left(b_{1}^{\prime} c^{\prime \prime}{ }_{2}-c_{x}^{\prime} b^{b^{\prime \prime}}\right)=0 . \tag{6}
\end{equation*}
$$

with one of the pencils

$$
\begin{align*}
& \alpha\left(a^{2} x c^{\prime} x-c^{2} x a_{1}^{\prime}\right)+\beta\left(b^{2} c^{\prime} x-c^{2} x b^{\prime} x\right)=0,1  \tag{10}\\
& a\left(a^{2} x c^{c^{\prime}} x-c^{2} x a^{\prime \prime} x\right)+\beta\left(b^{2} x c^{\prime \prime}{ }_{2}-c_{x}^{2} b^{\prime \prime}{ }_{2}\right)=0
\end{align*}
$$

As product of two projective pencils we find then besides $\Phi^{4}$ the plane $c_{a}^{\prime}=0$ or the plane $c^{\prime \prime}{ }_{a}=0$.
In connection with this we consider the curve $\mathscr{r}^{4}$, in which $\boldsymbol{p}^{4}$ is intersected by the arbitrary plane $\varphi$, as product of a cubic pencil with a quadratic pencil. The first, $\left(\mu^{3}\right)$, has two base-points $F_{1}, F_{2}$ on the intersection $f$ of $w$ with $c^{\prime}==0$ and seven base-points $F_{k}(k=3$ to 9 ) on $\varphi^{4}$. The second pencil, $\left(\varphi^{2}\right)$, has a base-point $G_{1}$ on $f$, the remaining three, $G_{k}(k=2,3,4)$ on $\rho^{4}$. The projectivity has been arranged in such a way that two homologous curves intersect in a point $Q$ of $f$.

The two pencils determine on $f^{4}$ the same involution $\left[^{5}\right.$; each group $Q_{x}(k=1$ to $\breve{5})$ consists of the intersections of $\%$ with one of the curves $\rho^{5}$.

We shall now determine the class of the curve enveloped by the straight lime $Q_{l} Q_{l}$; it is at the same time the order of the linecomplex formed by the bisecants of the curves $\rho^{\circ}$.
To this purpose we make use of the following general proposition ${ }^{1}$ ). If a curve $r^{n}$ is intersected by a pencl ( $\because 川$ ) in the groups of an involution $I^{s}$, the lines connecting the pairs envelop a cunve of class $\frac{1}{2}(n-1)(2 s-n)$.
From this it appears that the bisecants of the curves $\rho^{5}$ form $a$ complex of order nine.
§ 3. We arrive at the same result by paying attention to the pairs of lines of the pencil $\left(p^{2}\right)$. The straight line $G_{2}\left(Y_{0}\right.$ determines by its intersection $Q$ with $f$, a $\psi^{3}$, which meets the straight line $G_{1} G_{4}$ in three pounts of a curve $p^{5}$, hence $G_{1} G_{4}$ is a trisecant $t$. In the same way $G_{1} G_{2}$ and $G_{1} G_{3}$ appear to be trisecants These three straight hoes evidently replace nine bisecants. No biserant can belong to the plane pencil ( $G, \infty$ ) as it would have to he then on a pair of lines of $\left(\rho^{2}\right)$. From this it ensues that the comple, of the bisecants is of order nine.

In a plane passing through the straight line $c$, lies, as appeared above, a plane pencil of trisecants. As all the $p^{5}$ pass through the points $C_{1}, C_{2}$, any ray passing through one of these points, is bisecant for three different curves $\varrho^{5}$, which are indicated by the mersections of that ray with $\boldsymbol{\Phi}^{4}$. In any plane passing through $c$ the complex curve degenerates therefore into three plane pencils, which must each be counted thrice.

The complex cone of an arbitrary point $P$ bas three triple edlges. One of them is the ray, which the congruence $(1,3)$ of the trisecants sends through $P$, the other two connect $P$ with the cardinal points $C_{1}, C_{3}$.

For a point of the straight line $c$ the complex cone is replaced by the rational cubic cone, which projects the curve $\gamma^{3}$, this cone consists completely of trisecants and is therefore to be counted thrice.

If $P$ is taken on $T^{4}$, the complex cone degenerates into the cone of order four $S^{4}$, which projects the curve $9^{5}$ mdicated by $P$, consequently has a nodal edge, and a cone of order five $\Omega^{\circ}$, which is the locus of the sets of four bisecants which the curves $\rho^{5}$ send through $P$.

[^0]Proceedings Royal Acad. Amsterdam Vol. XIX

If $P$ lies on the curve $\gamma^{\prime}, \mathfrak{F}$ degenerates moreover into the plane pencil of the trisecants, lying in the plane ( $P c$ ) and a quadratic cone $\Re^{\circ}$.

This cone contains the bisecants belonging to the second system of generatrices of the hyperboloids (6). For they are indicated (cf. §1) by

$$
a a_{x}^{\prime}+\beta b_{x}^{\prime}+\gamma c_{x}^{\prime}=0 \quad, \quad a a_{2}^{\prime \prime}+\beta b_{x}^{\prime \prime} x+\gamma 0^{\prime \prime}{ }_{2}=0,
$$

they are therefore the bisecants of the curve $\gamma^{3}$, which according to (7) is determined by

$$
\left|\begin{array}{lll}
a_{x}^{\prime} & b_{2}^{\prime} & c_{x}^{\prime} \\
a_{x}^{\prime \prime} & b_{x}^{\prime \prime} & c_{2}^{\prime \prime}
\end{array}\right|=0
$$

The edges of ${ }^{32}$ therefore project $\gamma^{3}$ out of $P$ as centre.
§4. An involution $I^{\circ}$, which is produced by the intersection of a pencil of curves on a curve of genus $q$, has $2(\dot{g}+s-1)$ groups with a double point ${ }^{1}$ ). In an arbitrary plane lie therefore 14 touching bisecants; in other words the targents $r$ of the curves $\rho^{5}$ form a congruence of class fourteen.

If the plane of passes through $c$, ten of those tangents belong to the plane pencil of trisecants lying in it; they are the tangents at $\psi^{4}$ from the vertex of the plane pencil. The tangents in $C_{1}$ and $C_{2}$ at $\psi^{4}$ are therefore to be counted twice

- In order to be able to determine the order of the congruence [ $r$ ], we consider the twisted curve containing the ends $Q, Q^{\prime}$ of the chords lying on the complex cone of a point $P$. As this cone is of order 9 , the order of the curve in question amounts to 18; this ( $p^{18}$ has evidently nodes in the ends of the triple chord, lying on that cone ( $\$ 3$ ) and triple points in $C_{1}$ and $C_{2}$.

The planes connecting $Q$ and $Q^{\prime}$ with the arbitrary straight line $l$ agree in an involutorial correspondence $(18,18)$. of which the plane $(P l)$ represents an 18 -fold coincidence. The remaining 18 arise from pairs $Q^{\prime} \equiv \Omega$, consequently from tangents $r^{r}$; hence the order of $[r]$ is eighteen.

The points $C_{1}$ and $C_{2}$ are singular points of order one.
