J. de Vries, Bilinear congruences of twisted curves, which are determined by nets of cubic surfaces, in: KNAW, Proceedings, 18 I, 1915, Amsterdam, 1915, pp. 431-441

**Mathematics.** — “*Bilinear congruences of twisted curves, which are determined by nets of cubic surfaces.*” By Prof. JAN DE VRIES.

(Communicated in the meeting of May 29, 1915)

1. The base-curves  $q^9$  of the pencils belonging to a general net  $[\Phi^3]$  of cubic surfaces, form a bilinear congruence. For through an arbitrary point passes *one* curve  $q^9$ , and the involution of the second rank, which the net determines on an arbitrary straight line, has *one* neutral pair, so that there is *one*  $q^9$  for which that straight line is bisecant.

The 27 base-points of the net are fundamental points of the congruence. Any straight line  $f$  passing through one of those points  $F$  is *singular bisecant*; for through any point of  $f$  passes a  $q^9$ , at the same time containing  $F$ . As the points of support of the curves resting on  $f$  form a parabolic involution,  $f$  may be called a parabolic bisecant.

Let  $t$  be a trisecant of a  $q^9$ ; through an arbitrary point of  $t$  passes *one*  $\Phi^3$ , and this surface contains *all* the points of  $t$ . By the remaining surfaces of the net,  $t$  is intersected in the triplets of an involution; consequently  $t$  is a *singular trisecant*. The singular trisecants therefore form a congruence of rays; it is at the same time the congruence of the straight lines lying on the surfaces of the net.

A curve  $q^9$  has 18 apparent nodes, is therefore of genus 10. The cone of order eight  $\mathfrak{S}^8$ , projecting it out of one of the points  $F$  has therefore 11 double edges  $t^1$ ).

Any point  $F$  is a singular point for the congruence  $[t]$ , consequently vertex of a cone  $\mathfrak{Z}$  formed by trisecants  $t$ . With  $\mathfrak{S}^8$  this cone has, besides the 26 straight lines  $FF'$  to the remaining fundamental points, the 11 double edges of  $\mathfrak{S}^8$  in common. Consequently  $\mathfrak{Z}$  is a cone of order six; the congruence  $[t]$  has therefore 27 *singular points of order six*.

The trisecants of a  $q^9$  form a ruled surface, on which  $q^9$  is an elevenfold curve. With an arbitrary surface  $\Phi^3$  this ruled surface has moreover the 27 straight lines of  $\Phi^3$  in common; the complete section is consequently a figure of order 126, and the ruled surface in question has the order 42.

Let us now consider the axial ruled surface  $\mathfrak{A}$ , formed by the rays of the congruence  $[t]$  resting on a straight line  $a$ . With an arbitrary  $q^9$  it has first in common the 27 sextuple points  $F$ ; the

1) A curve  $\epsilon^n$  with  $h$  apparent nodes is intersected in each of its points by  $h - (n-2)$  trisecants.

remaining intersections lie three by three on the 42 trisecants of  $\varrho^9$ , resting on  $a$ . From this it follows that  $\mathfrak{U}$  is a ruled surface of order 32. As an arbitrary point bears *eleven* straight lines  $t$ ,  $a$  is elevenfold straight line of  $\mathfrak{U}^{32}$ , and a plane passing through  $a$  contains moreover 21 straight lines  $t$ . *The singular trisecants form therefore a congruence (11, 21).*

In order to investigate whether the congruence  $[\varrho^9]$  possesses other singular bisecants besides, we consider the surface  $\mathfrak{H}$ , which contains the points of support of the chords, which the curves  $\varrho^9$  send through a given point  $P$ . A straight line  $r$  passing through  $P$ , is, in general, chord of *one*  $\varrho^9$ , therefore contains two points of  $\mathfrak{H}$  lying outside  $P$ . One of those points of support comes in  $P$ , as soon as  $r$  becomes chord of the  $\varrho^9$ , passing through  $P$ . The cone  $\mathfrak{K}^3$  projecting this  $\varrho^9$  out of  $P$ , is therefore the cone of contact of the octuple point  $P$  and  $\mathfrak{H}$  is of order 10. The 11 straight lines  $t$  passing through  $P$  are nodal edges of  $\mathfrak{K}^3$  and at the same time nodal lines of  $\mathfrak{H}^{10}$ . The complete section of these two surfaces consists of the 11 double lines mentioned, the curve  $\varrho_P^9$  and the 27 straight lines  $PF$ . From this it ensues that the straight lines  $f$  are the only singular bisecants.

With an arbitrary  $\varrho^9$   $\mathfrak{H}^{10}$  has the points of support of the 18 chords in common, which the curve sends through  $P$ ; the remaining 54 intersections lie in the points  $F$ ; consequently  $\mathfrak{H}^{10}$  has nodes in the 27 fundamental points.

2. If two surfaces  $\Phi^3$  touch each other, the point of contact  $D$  is node of their section  $\sigma^9$  and at the same time node of a surface belonging to the net. The locus of  $D$  is a curve  $\sigma^{24}$ . In order to find the locus of the nodal curves  $\sigma^9$ , we consider two pencils of the net. Each surface of the first pencil has 72 points  $D$  in common with  $\sigma^{24}$ , is therefore touched by 72 surfaces of the second pencil; by this a correspondence (72,72) is determined between those pencils. The intersections of homologous surfaces with a straight line  $l$  are homologous points in a correspondence (216,216); and both pencils produce therefore a figure of order 432. But the surface that the pencils have in common has been assigned 72 times to itself; the real product is therefore of order 216 only. From this it appears that *the nodal curves  $\sigma^9$  form a surface of order 216,  $\Delta^{216}$ .*

An arbitrary  $\varrho^9$  can intersect this surface in the points  $F$  only; consequently  $\Delta^{216}$  has the fundamental points as 72-fold points.

3. The pencils mentioned above are brought in a correspondence

(3,3), when each two surfaces, intersecting on a straight line  $l$ , are considered as homologous. It is found then that the locus of the curves  $\varrho^9$ , resting on  $l$ , is a surface  $\mathcal{A}$  of order *nine*, which has the fundamental points as *triple points*.<sup>1)</sup>

Two straight lines are therefore intersected by *nine* curves  $\varrho^9$ .

The curves  $\varrho^9$ , intersecting a straight line  $f$ , form therefore a surface of order six, with nodes  $F$ .

A plane passing through  $l$ , intersects  $\mathcal{A}^9$  moreover along a curve  $\lambda^8$ , the latter has in common with  $l$  the points of support of the curve  $\varrho^9$ , which has  $l$  as chord (*nodal curve* of  $\mathcal{A}^9$ ). In each of the remaining points of intersection of  $l$  with  $\lambda^8$  the plane is touched by curves  $\varrho^9$ . The points, in which a plane  $\varphi$  is touched by curves of the congruence lie therefore in a curve  $\varrho^6$ . The latter is the *curve of coincidence of the nonuple involution* which  $[\varrho^9]$  determines in  $\varphi$ ; this involution possesses no exceptional points; each point belongs to *one* group.

As each point of intersection of  $\varphi^6$  with a surface  $\mathcal{A}^9$  belonging to an arbitrary straight line  $l$  indicates a curve  $\varrho^9$ , which touches  $\varphi$  and rests on  $l$ , the curves  $\varrho^9$  touching  $\varphi$  form a surface  $\Phi^{54}$ . This surface has moreover in common with  $\varphi$  a curve  $\varphi^{42}$ ; as the latter can only touch the curve  $\varphi^6$ , there are 126 curves  $\varrho^9$ , *osculating a given plane*.

If the curve  $\varphi^6$  is brought in connection with the surface  $\Psi^{54}$ , belonging to a plane  $\psi$ , then it appears that *two arbitrary planes are touched by 324 curves  $\varrho^9$* .

4. If the surfaces of a net  $[\Phi^3]$  have the straight line  $q$  in common, the *base-curves*  $\varrho^8$  of the pencils form a bilinear congruence with *singular quadrisecant*  $q$ . As a  $\varrho^8$  is cut by a surface  $\Phi$ , outside  $q$ , in 20 points, the congruence has 20 fundamental points  $F$ .

Each point  $S$  of  $q$  is singular; the  $\infty^1$  curves  $\varrho^8$  passing through  $S$  form a monoid  $\Sigma^3$  belonging to the net, with nodal point in  $S$ . In order to confirm this more specially we consider two pencils of the net, and make them projective by associating any two surfaces, which touch in  $S$ . The figure which they produce then consists of the common figure of the pencils and the monoid  $\Sigma^3$ .

If  $\Sigma^3$  is represented by central projection out of  $S$  on a plane  $\varphi$ , the images of the curves  $\varrho^8$  form a pencil of curves  $\varphi^7$ . The image of the quadrisecant is triple base-point, the images of the five trisecants  $t$ , which a  $\varrho^8$  sends moreover through  $S$ , are double base-points. The remaining 20 base-points are the images of the points

<sup>1)</sup> A  $\varrho^9$  which does not intersect  $l$  will cut  $\mathcal{A}^9$  only in the 27 points  $F$ .

$F$ . The five straight lines  $t$  lie, like  $q$ , entirely on  $\Sigma^3$ ; they are apparently *singular trisecants*. Each straight line  $t$  is intersected by the curves  $\varrho^8$  in  $S$ , and in a pair of an involution.

Two monoids have the straight line  $q$  and a  $\varrho^8$  in common. Consequently in general a curve of the congruence is determined by two of its intersections with  $q$ . The sets of four points of support form therefore an involution of the second rank. So there are on  $q$  three pairs of points, which each bear  $\infty^1$  curves  $\varrho^8$ ; in other words, the net contains *three binodal surfaces*, of which the two nodes lie on  $q$ . We may further observe that  $q$  is stationary tangent of *six*  $\varrho^8$  and bitangent of *four*  $\varrho^8$ .

Each trisecant  $t$  of a  $\varrho^8$  is singular (§ 1); the straight lines  $t$  form a congruence of order 8, with 20 singular points  $F$ . The cone  $\mathfrak{F}^7$ , with vertex  $F$ , which projects a  $\varrho^8$ , has 8 double edges and contains 19 straight lines  $FF'$ ; from this it ensues that the straight lines passing through  $F$  form a cone  $\mathfrak{S}^8$ , so that  $F$  appears to be a *singular point of order five*.

In any plane passing through  $q$  lie 6 chords of a  $\varrho^8$ , through any point of  $q$  pass 8 chords. The straight lines resting on  $q$  and twice on  $\varrho^8$ , form therefore a ruled surface of order 14. As they belong to the trisecants of the figure  $(q, \varrho^8)$ , the trisecants of  $\varrho^8$  must form a ruled surface of order 28.

Let us now again consider the axial ruled surface  $\mathfrak{A}$ , formed by the trisecants resting on the straight line  $a$ . With a definite  $\varrho^8$   $\mathfrak{A}$  has the 20 quintuple points  $F$  and 28 triplets of points of support in common; from this it ensues that  $\mathfrak{A}$  is of order 23. *The singular trisecants consequently form a congruence (8, 15).*

5. The surface  $\mathfrak{H}$  is here of order 9; it contains  $q$  and has 20 nodes  $F$  (§ 1). Its section with the cone,  $\mathfrak{F}^7$ , which projects the  $\varrho^8$  laid through  $P$ , consists of that curve, 8 singular trisecants (which are nodal lines for both surfaces) the 20 singular bisecants  $PF$  (each with a parabolic involution of points of support) and moreover three straight lines  $b$ , which apparently must also be *singular bisecants*. These straight lines we find moreover by paying attention to the intersections of  $\mathfrak{F}^7$  with  $q$ ; to them belong the four points, which  $q$  has in common with the  $\varrho^8$  projected by that cone. If  $S$  is one of the remaining three intersections the straight line  $PS$  belongs to a  $\Phi^3$  of the net, is consequently cut by that net in the pairs of an involution and is therefore bisecant of  $\infty^1$  curves  $\varrho^8$ .

For a point  $S$  of  $q$   $\mathfrak{H}$  consists of the monoid  $\Sigma^3$  and a *cone of order six*. For, a bisecant of a  $\varrho^8$  not laid through  $S$  is at the same

time bisecant of a  $\varrho^8$  belonging to  $\Sigma^3$ , consequently a singular bisecant  $b$ . The locus of the straight lines  $b$  drawn through  $S$  forms therefore with  $\Sigma^3$  the surface  $\Pi$ . An arbitrary plane consequently contains six straight lines  $b$ , and the singular bisecants form a congruence (3,6). The three rays  $b$  out of a point  $P$  lie in the plane  $(Pq)$ ; the six rays in a plane  $\tau$  meet in the point  $(\tau q)$ .

The curves  $\varrho^8$  meeting a straight line  $l$  form again a surface  $A^9$ . On it  $q$  is triple straight line, for each monoid  $\Sigma^3$  contains three curves resting on  $l$  and meeting in  $S$ . Two surfaces  $A$  have besides  $q$  the 9 curves  $\varrho^8$  in common, resting in the two straight lines  $l$ . The points  $F$  appear this time again to be triple.

In a plane  $\varphi$  the congruence  $[\varrho^8]$  determines an *octuple involution*, which possesses a *singular point of order three* (intersection  $S$  of  $q$ ). The curve of coincidence  $\varphi^6$  (§ 3) has now a *node*  $S$ .

As  $A^9$  and  $\varphi^6$  have now, outside  $S$ , 48 points in common, the curves  $\varrho^8$ , which touch the plane  $\varphi$ , form a surface  $\Phi^{48}$ . On it  $q$  is a 16-fold straight line; for the monoid that has an arbitrary point of  $q$  as vertex, cuts  $\varphi^6$ , outside  $q$ , in 16 points. The plane  $\varphi$  cuts  $\Phi^{48}$  moreover along a curve  $\varphi^{36}$  with 12-fold point  $S$ . The curves  $\varphi^{36}$  and  $\varphi^6$  have 24 intersections in  $S$ ; as their remaining common points must coincide in pairs, there are 96 curves  $\varrho^8$  osculating  $\varphi$ .

The curve  $\varphi^6$  has with the surface  $\Psi^{48}$  (belonging to a plane  $\psi$ )  $6 \times 48 - 2 \times 16 = 256$  points in common outside  $q$ ; there are consequently 256 curves  $\varrho^8$ , which touch two given planes.

**6.** If the surfaces  $\Phi^3$  of a net have two non-intersecting straight lines  $q$  and  $q'$  in common, they determine a bilinear congruence of twisted curves  $\varrho^7$ , of genus four, for which  $q$  and  $q'$  are singular quadrisecants; it has 13 fundamental points  $F$ . The curves  $\varrho^7$  have 11 apparent nodes.

If the monoid  $\Sigma^3$  containing the curves  $\varrho^7$ , which intersect  $q$  in  $S$ , is represented in the usual way, the system of those curves passes into a pencil of curves  $\varphi^6$ , which has a triple base-point on  $q$  and double base-points in the intersections of three other straight lines  $t$  of the monoid; the remaining base-points are the images of the points  $F$ , and the intersections of the two straight lines  $b^*$ , which may moreover be drawn on  $\Sigma^3$  through  $S$  (and which apparently rest on  $q'$ ). The straight lines  $b^*$  are *singular bisecants* (parabolic bisecants), the straight lines  $t$  are *singular trisecants*. The locus of the singular bisecants  $b^*$  is a ruled surface of order four with nodal lines  $q$  and  $q'$ .

Through an arbitrary point  $P$  pass six singular trisecants; they

are nodal lines of the surface  $\Pi^8$  determined by  $P$  and nodal edges of the cone  $\mathfrak{K}^6$ , which projects the curve  $q^7$  laid through  $P$ . These two surfaces have besides that  $q^7$  and the six straight lines  $t$ , moreover the 13 parabolic bisecants  $PF$  and *four singular bisecants*  $b$  in common. The straight lines  $b$  are found back if  $\mathfrak{K}^6$  is brought to intersection with  $q$  and  $q'$ ; on each of the singular quadrisecants rest therefore two straight lines  $b$ .

Each point of  $q$  or  $q'$  bears a cone of order 5 (completing  $\Sigma^3$  into a surface  $\Pi^8$ ) formed by singular bisecants. *The singular bisecants consequently form two congruences (2,5).*

The locus of the trisecants of the figure  $(q, q', q^7)$  consists of four ruled surfaces, together forming a figure of order 42. The straight lines intersecting  $q, q'$  and  $q^7$  apparently form a ruled surface  $\mathfrak{K}^6$ . The bisecants of  $q^7$  resting on  $q$  or on  $q'$  lie on a  $\mathfrak{K}^8$  with quintuple straight line. Consequently the trisecants  $t$  of  $q^7$  will form a  $\mathfrak{K}^{20}$  (with sextuple curve  $q^7$ ).

According to the method followed above (§§ 1, 4) we find now that *the singular trisecants  $t$  form a congruence (6, 10)*, possessing in the 13 fundamental points  $F$  singular points of order six.

On two arbitrary straight lines nine curves of the congruence rest now too. The surface  $\mathcal{A}^9$  has two triple straight lines,  $q$  and  $q'$ . In a plane  $\varphi$  arises a *septuple involution* with a curve of coincidence  $\varphi^8$  possessing *two nodes*, where the involution has *singular points of order three*. The curves  $q^7$  touching  $\varphi$ , form a  $\Phi^{12}$  with 14-fold straight lines  $q$  and  $q'$ .

There are 70 curves  $q^7$  *osculating* a plane  $\varphi$ , and 196 curves *touching two given planes*.

7. If the surfaces  $\Phi^3$  of a net have a conic  $\sigma^2$  in common they determine a bilinear congruence of *twisted curves*  $q^7$ , of genus *five*. Every  $q^7$  rests in six points on the singular conic  $\sigma^2$ . The congruence possesses consequently 15 *fundamental points*  $F$ .

In representing the monoid  $\Sigma^3$ , containing the curves  $q^7$ , which intersect  $\sigma^2$  in a point  $S$ , the system of those curves passes into a pencil of curves  $\varphi^6$ . They have five nodes in the intersections of the singular trisecants  $t$ , meeting in  $S$ , the remaining base-points are the images of the 15 points  $F$ , and the intersection of the straight line  $b^*$  of  $\Sigma^3$ , which forms with the 5 straight lines  $t$  the set of six straight lines passing through  $S$ . Apparently  $b^*$  is here also a *singular bisecant* (parabolic bisecant).

The surface  $\Pi^8$  belonging to a point  $P$  and the corresponding cone  $\mathfrak{K}^6$  have in common a  $q^7$ , five singular trisecants  $t$  (nodal lines

for both surfaces), the 15 parabolic bisecants  $PF$  and *six singular bisecants*  $b$ .

For a point  $S$  of  $\sigma^2 \Pi^3$  consists of the monoid  $\Sigma^3$  and a cone of order five formed by straight lines  $b$ . Hence *the singular bisecants*  $b$  form a congruence (6, 10).

Let us now consider the straight lines which intersect the figure  $(\rho^7, \sigma^2)$  thrice, consequently form together a figure of order 42. Any point of  $\sigma^2$  bears 10 chords of  $\rho^7$ ; in the plane  $\sigma$  of that conic there are 6 of them, viz. the straight lines connecting the 6 intersections of  $\sigma^2$  and  $\rho^7$  with the point  $R$ , which  $\rho^7$  has moreover in common with  $\sigma$ . The chords of  $\rho^7$  meeting  $\sigma^2$  consequently form a  $\mathfrak{X}^{20}$ . The chords of  $\sigma^2$  meeting  $\rho^7$ , form the plane pencil  $(R, \sigma)$ . Consequently the trisecants of  $\rho^7$  form a  $\mathfrak{X}^{15}$ .

In connection with this we easily find now that the *singular trisecants* form a congruence (5,10) possessing 15 singular points  $F$  of order four.

The surface  $\mathcal{A}^9$  has now a triple conic,  $\sigma^2$ , and 15 triple points  $F$ . In a plane  $\rho$   $[\rho^7]$  determines again a septuple involution with two singular points of order three. In connection with this we find for this congruence  $[\rho^7]$  the same characteristic number as for the  $[\rho^7]$  treated in § 6.

**8.** Passing on to congruences of twisted curves  $\rho^6$ , we suppose in the first place, that the surfaces of  $[\Phi^3]$  have three non-intersecting straight lines  $q, q', q''$  in common. They are then *singular quadrisecants* of the congruence  $[\rho^6]$ ; consequently the curves  $\rho^6$  (genus one) pass through *six fundamental points*  $F$ .

The curves  $\rho^6$  intersecting  $q$  in  $S$  form again a monoid  $\Sigma^3$ . They are represented by a pencil  $(\rho^6)$ , having a triple base-point on  $q$  and double base-points in the intersections of two straight lines  $t$ . To the base belong further the images of the points  $F$  and the intersections of two straight lines  $b^*$  (singular bisecants).

The sixth straight line of  $\Sigma^3$ , passing through  $S$ , is component part of a *degenerate curve*  $\rho^6$ . It is the transversal  $d$  of  $q'$  and  $q''$  passing through  $S$ ; for through an arbitrary point of that transversal pass  $\infty^1$  surfaces  $\Phi^3$  having  $d$  in common and therefore intersecting moreover along a curve  $\sigma^6$  (of genus one), which has  $q, q', q''$  as trisecants. The planes  $(dq')$  and  $(dq'')$  each intersect  $\Sigma^3$  along one of the straight lines  $b^*$ .

The ruled surface  $\mathcal{D}^2$  with directrices  $q, q', q''$  contains all the straight lines  $d$  forming the second system of straight lines. With a monoid  $\Sigma^3$   $\mathcal{D}^2$  has three straight lines  $d$  in common of which one

passes through  $S$ . Consequently there lie on  $\Sigma^3$  two curves  $\sigma^6$ , which pass through  $S$ . The locus  $\Delta$  of the curves  $\sigma^6$  has consequently three nodal lines  $q, q', q''$ ; its section with a  $\Sigma^3$  consists further of three curves  $\sigma^6$ , is therefore of order 21. Hence  $\Delta$  is a surface of order seven.

The figures  $(d, \sigma^6)$  determine on  $q$  a correspondence  $(3, 2)$ ; so there lie on  $q$  five points  $D \equiv (d, \sigma^6)$ . The locus of the points  $D$  is therefore a twisted curve  $(D)^6$ , intersecting each of the straight lines  $q, q', q''$  five times.

Now  $\mathfrak{D}^2$  and  $\Delta^7$  have the three straight lines  $q$  and the curve  $(D)^6$  in common, consequently another figure of order two. This figure must consist of two straight lines  $d$ , hence there is a figure of  $[\nu^6]$  consisting of two straight lines  $d$  and a curve  $\sigma^6$ . This curve has  $q, q', q''$  as bisecants and intersects  $\mathfrak{D}^2$  moreover in two points  $D$ .

Through an arbitrary point  $P$  pass five singular trisecants; they are nodal lines of  $\mathfrak{H}^7$  and  $\mathfrak{K}^5$ . These surfaces have moreover in common the curve  $\rho_P^6$  laid through  $P$ , the six parabolic bisecants  $P\bar{F}$  and three straight lines  $b$ . The straight lines  $b$  are determined by the points which the straight lines  $q$  outside the curve  $\rho_P^6$  have in common with the cone  $\mathfrak{K}^5$ ; hence they are *singular bisecants*.

If  $P$  is supposed to be on  $q$ ,  $\mathfrak{H}^7$  is replaced by the figure composed of  $\Sigma^3$  and a cone  $(b)^4$ . *The singular bisecants form consequently three congruences (1, 4).*

The locus of the straight lines which intersect a figure  $(\rho^6, q, q', q'')$  thrice, consists of the hyperboloid  $(q, q', q'')$ , three ruled surfaces  $\mathfrak{K}^4$  with nodal lines  $q, q'$  and the ruled surface of the trisecants of  $\rho^6$ ; this is therefore of order 16.

From this it is now deduced, in the way followed before, that *the singular trisecants form a congruence (5, 6) possessing six singular points  $\bar{F}$  of order three.*

The surface  $\mathcal{A}^9$  has three triple straight lines  $q, q', q''$ . In a plane  $\varphi$  the congruence  $[\rho^6]$  determines a *sextuple involution with three singular points of order three*, which are at the same time nodes of the curve of coincidence  $\varphi^6$ . The curves  $\varrho^6$ , touching  $\varphi$ , form a  $\Phi^{36}$  with 12-fold straight lines  $q, q', q''$ . There are 48 curves  $\varrho^6$ , *osculating one plane*, and 144 curves *touching two planes*.

9. Let us now consider the case that all the surfaces of the net  $[\Phi^9]$  have in common a conic  $\sigma^2$  and a straight line  $q$  not intersecting it. Any two surfaces then determine a *twisted curve*  $\rho^6$ , which rests in six points on  $\sigma^2$ , in four points on  $q$ . A third surface intersects  $\rho^6$  moreover in eight points. The congruence  $[\rho^6]$  possesses

therefore *eight fundamental points*  $F$ . The curves  $\varrho^0$  have eight apparent nodes, they are consequently of genus *two*.

The monoid  $\Sigma^3$  belonging to a point  $S$  of the *singular quadrisecant*  $q$  contains a *singular trisecant* passing through  $S$ . From the image of  $\Sigma^3$  it appears that the remaining four straight lines of  $\Sigma^3$  passing through  $S$  are *singular bisecants*  $b^1$ .

The curves  $\varrho^0$  intersecting the singular conic  $\sigma^2$  in a point  $S^*$  also form a monoid  $\Sigma^3$ . These curves are represented by a pencil ( $\varrho^5$ ), which has double base-points in the intersections of the *four singular trisecants*  $t$  meeting in  $S^*$ . The simple base-points are the images of the 8 points  $F$  and the intersection of a *singular bisecant*  $b^*$ .

The sixth straight line passing through  $S^*$  must be component part of a *compound*  $\varrho^0$ . It must cut  $\sigma^2$  and  $q$ , belongs therefore to the plane pencil in the plane  $\sigma$  of  $\sigma^2$ , which has the point  $Q$  of  $q$  as vertex.

Any ray  $d$  of that plane pencil is component part of a degenerate  $\sigma^0$ , for an arbitrary point of  $d$  determines a pencil ( $\Phi^3$ ) of which all figures pass through  $d$ , consequently have a curve  $\varrho^5$  in common besides, which intersects  $\sigma^2$  four times,  $q$  three times, consequently possesses four apparent nodes. To the surfaces  $\Phi^3$  passing through the figure  $(\sigma^2, q, d, \sigma^5)$  belongs the figure composed of the plane  $\sigma$  and the *hyperboloid*  $\mathfrak{D}^2$  passing through  $q$  and the points  $F$ ; this degenerate figure apparently replaces the monoid belonging to  $Q$ . The hyperboloid  $\mathfrak{D}^2$  is *the locus of the curves*  $\sigma^5$ ; its intersection  $\sigma^2$  on  $\sigma$  contains the points  $D \equiv (d, \sigma^5)$ ; all curves  $\sigma^5$  pass through the four intersections of  $\sigma^2$  with  $\sigma$ .

From the consideration of the surfaces  $\Pi^7$  and  $\mathfrak{R}^5$ , which are determined by a point  $P$  it follows readily that  $P$  bears five singular bisecants  $b$ . Four of these straight lines rest on  $\sigma^2$ , the fifth on  $q$ . Any point of  $\sigma^2$  or of  $q$  is the vertex of a cone of order four, formed by straight lines  $b$ . The *singular bisecants* consequently form two congruences; a *congruence* (1,4) with directrix  $q$ , a *congruence* (4,8) with singular curve  $\sigma^2$ .

The singular trisecants  $t$  form a congruence possessing eight singular points,  $F$ , of order three. The trisecants of a  $\varrho^0$  form a ruled surface  $\mathfrak{R}^{12}$ . In connection with this we find that the straight lines  $t$  determine a *congruence* (4,6).

As  $[\varrho^0]$  again intersects a plane  $\varphi$  along a *sextuple involution* with three singular points of order three, we find for the characteristic numbers connected with it the same values as in § 8.

**10.** A net  $[\mathfrak{C}^3]$ , of which the figures have a cubic  $\sigma^3$  (or a

degeneration of it) in common, determines a congruence of twisted curves  $\varrho^6$ , of genus *three*, intersecting the singular curve  $\sigma^3$  eight times <sup>1)</sup>. The congruence possesses accordingly *ten fundamental points*  $F$ .

As  $\varrho^6$  has seven apparent nodes,  $\sigma^3$  is intersected in each of its points  $S$  by *three singular trisecants*  $t$ . Using the image of the monoid  $\Sigma^3$  belonging to  $S$ , we find that the remaining three straight lines of  $\Sigma^3$  meeting in  $S$  are *singular bisecants*  $b^*$ .

Through an arbitrary point  $P$  pass seven singular bisecants  $b$ . Each point of  $\sigma^3$  is vertex of a cone of order four formed by straight lines  $b$ . From this it ensues that *the singular bisecants form a congruence* (7,12).

The *singular trisecants* form a congruence (3,6) with ten singular points;  $F$ , of order three.

The characteristic numbers, connected with the surface  $A^9$ , have the same values as with the congruence [ $\varrho^6$ ] already dealt with.

11. The surfaces of a net [ $\Phi^3$ ], which have a plane curve  $\sigma^3$  in common, determine a congruence of *twisted curves*  $\varrho^6$  of genus *four*, which possesses *twelve fundamental points*  $F$ .

As  $\varrho^6$  has now six apparent nodes, each point  $S$  of the singular curve  $\sigma^3$  bears *two singular trisecants*.

To the surfaces  $\Phi^3$  passing through a figure ( $\sigma^3, \varrho^6$ ) belongs a figure consisting of the plane  $\sigma$  of  $\sigma^3$  and a hyperboloid;  $\varrho^6$  is therefore the complete section of a hyperboloid with a cubic surface. In connection with this the curves  $\varrho^6$  intersecting  $\sigma^3$  in a point  $S$ , form a *hyperboloid*  $\Sigma^2$ , passing through the points  $F$ . The surfaces  $\Sigma^2$  form a pencil <sup>2)</sup> with *base-curve*  $\beta^4$ , which determines in  $\sigma$  a pencil of conics  $\varrho^2$ . Any point of the plane  $\sigma$  bears therefore a *figure consisting of a*  $\varrho^2$  *and the curve*  $\beta^4$ .

The section of  $\sigma$  with the surface  $A$  belonging to the straight line  $l$  consists of the nodal curve  $\sigma^3$  and the conics  $\varrho^2$  intersected by  $l$ ; hence  $A$  is of *order eight*.

Two surfaces  $A^8$  have the singular curve  $\sigma^3$ , the curve  $\beta^4$ , and eight curves  $\varrho^6$  in common.

<sup>1)</sup> If  $\sigma^3$  is replaced by a conic  $\sigma^2$  and a straight line  $s$  intersecting it, we understand easily that any  $\varrho^6$  has five points in common with  $\sigma^2$ , and three points with  $s$ .

<sup>2)</sup> The net [ $\Phi^3$ ] may be represented by the equation

$$a_x^3 + \lambda (a_x^3 + b_x^2 x_4) + \mu (a_x^3 + c_x^2 x_4) = 0.$$

Through a point of  $x_4 = 0$  passes the pencil for which  $1 + \lambda + \mu = 0$ . It consists therefore of the plane  $x_4 = 0$ , and the pencil  $\lambda (b_x^2 - c_x^2) - c_x^2 = 0$ , with base-curve  $b_x^2 = 0, c_x^2 = 0$ .

The sextuple involution, which  $[\varrho^6]$  determines in a plane  $\varphi$ , has three singular points  $S$  of order two lying in a straight line  $s$  and (in the intersections of  $\beta^4$ ) four singular points of order one, which are completed into sets of six by the pairs of an involution lying on  $s$ .

Any trisecant  $t$  of a  $\varrho^6$  is trisecant of  $\infty^2$  curves of the congruence and in particular of a figure  $(\varrho^2, \beta^4)$ . The congruence of the singular trisecants is therefore identical with the congruence of the chords of  $\beta^4$ , is consequently a  $(2, 6)$ .

The cone projecting a  $\varrho^6$  out of one of its points has in common with  $\sigma^3$  the 6 intersections of the two curves; the remaining 9 points determine each a singular bisecant  $b$ .

The surface  $\Pi^7$  belonging to a point  $S$  of  $\sigma^3$  consists of  $\Sigma^2$ , the plane  $\sigma$  (of which any straight line is singular bisecant) and a cone  $(b)^4$ . Consequently the singular bisecants  $b$  form a congruence  $(9, 12)$ .

A plane  $\varphi$  contains a curve  $\varphi^5$  being the locus of the points of contact of curves  $\varrho^6$ . As  $\varphi^5$  has 34 points in common with  $\mathcal{A}^8$ , outside  $\sigma^3$ , the curves  $\varrho^6$  touching  $\varphi$  form a  $\Phi^{34}$ , which is moreover intersected by  $\varphi$  in a curve  $\varrho^{24}$ . As  $\varphi^5$  is intersected by an arbitrary  $\Sigma^2$  in 10 points,  $\sigma^3$  is decuple curve of  $\Phi^{34}$ ; so  $\varrho^{24}$  has three octuple points  $S$ . From this it ensues further that  $\varphi^5$  and  $\varrho^{24}$ , apart from the points  $S$ , have 96 points in common, so that  $\varphi$  is osculated by 48 curves  $\varrho^6$ .

As  $\varphi^5$  has outside  $\sigma^3$  140 points in common with  $\mathcal{W}^{34}$  there are 140 curves  $\varrho^6$  touching two planes.

The bilinear congruences of twisted curves  $\varrho^5$  and  $\varrho^4$ , which are determined by nets of cubic surfaces I have considered in communications published in volume XVII, p. 1250, in volume XVIII, p. 43 and in vol. XVI, p. 733 and 1186 of these *Proceedings*. The congruence of twisted cubics determined by a  $[\Phi^3]$  was extensively treated by STUYVAERT (Bull. Acad. de Belgique, 1907, p. 470—514).

**Mathematics.** — “Associated points with respect to a complex of quadrics.” By CHS. H. VAN OS. (Communicated by Professor JAN DE VRIES).

(Communicated in the meeting of May 29, 1915).

Let a triply infinite linear system (*complex*) be given of quadrics  $\Phi^2$ . The surfaces passing through a point  $P$  form a net and have moreover seven points  $Q$  in common. If we associate those points to  $P$  we get a correspondence, which will be considered here.
