curves $A$ and $B$ need at most be of degree ( $r-m$ ) and ( $r-n$ ). If this is not the case, however, the terms of the highest degree of $A F_{1}$ and $B F_{2}$ will cancel each other; as the terms of the highest degree in $F_{1}$ and $F_{2}$ have no common factor, those of $A F_{1}$ and $B F_{2}$ will be divisible by those of $F_{1} F_{2}$.

Let us therefore suppose

$$
\begin{aligned}
& A F_{1} \equiv A^{\prime} F_{1} F_{2}+A^{\prime \prime} F_{2} \\
& B F_{2} \equiv B^{\prime} F_{1} F_{2}+B^{\prime \prime} F_{2},
\end{aligned}
$$

in which we extend the division by $F_{1} F_{2}$ only so far that the terms of the highest degree in $A F_{1}$ and $B F_{2}$ have disappeared, we have

$$
A^{\prime} \equiv-B^{\prime}
$$

So we find

$$
F_{\mathrm{s}} \equiv A^{\prime \prime} F_{1}+B^{\prime \prime} F_{2},
$$

in which $A^{\prime \prime}$ and $B^{\prime \prime}$ are of a lower degree than $A$ and $B$. So we may go on till we find

$$
F_{\mathrm{s}} \equiv A(c) F_{1}+B(c) F_{\mathrm{z}}
$$

in which $A^{(c)}$ and $B^{\left({ }^{\prime}\right)}$ are at most of degree $(r-m)$ and ${ }^{*}(r-n)$.

## Mathematics. - "A bilinear congruence of rational twisted quintics".

 By Professor Jan de Vries.(Communicated in the meeting of March 27, 1915).

1. The base-curves of the pencils belonging to a net [ $\boldsymbol{\Phi}^{3}$ ] of cubic surfaces form a bilinear congruence. For through an arbitrary point passes only one curve, and an arbitrary straight line is chord of one curve; for the involution $I_{2}{ }^{3}$, which the net determines on that line, has one neutral pair of points.

We shall consider the particular net, the base of which consists of the twisted cubic $\sigma^{3}$, the straight line $s$ and the points $F_{1}, F_{y}, F_{3},{ }^{1}$ ) The surfaces $\boldsymbol{\Phi}^{\mathbf{3}}$, which connect this basis with a point $P$ have moreover a twisted quintic $\rho^{5}$ in common. A bilinear congruence $\left[\boldsymbol{\rho}^{5}\right]$ is therefore determined by [ $\left.\boldsymbol{I}^{3}\right]$. A plane passing through $s$ intersects two arbitrary surfaces of the net in two conics; of their intersections three lie on $\sigma^{\text {b }}$, the fourth belongs to $\varrho^{5}$; consequently this curve has four points in common with $s$, is therefore rational.

The straight line $s$ is apparently a singular quadrisecant.
The figure consisting of $s, \sigma^{3}$ and $\rho^{5}$ is, as complete intersection

[^0]of , two $\Phi^{3}$, of rank, 36. As $\sigma^{3}$ is of rank four and $\rho^{5}$, as rational ${ }^{\prime}$ curve of rank eight, while $s$ has four points in common with $\rho^{6}$, $e^{5}$ and $\sigma^{3}$. will have eight points in common. We can therefore determine the congruence $\left[0^{\circ}\right]$ as the system of rational curves $9^{6}$ passing through three fundamental points $F_{1}, F_{3}, F_{3}$, cutting the singular curve $\sigma^{3}$ eight times and having $s$ as sinqular quadrisecant.

It incidentally follows from this, that $\varrho^{5}$ may satisfy 20 simple conditions.
2. Let $b$ be a bisecant of $\sigma^{3}$, resting on $s$, all $\Phi^{2}$ passing through a point of $b$ have this line in common, therefore determine a pencil the base of which consists of $s, b, \sigma^{2}$ and a rettional $Q^{4}$, which has three points wilh $s$ six points with $\sigma^{3}$, consequently one point in common with $b$.

There are also figures of $\left[\rho^{5}\right]$ consisting of a conce $\rho^{2}$ and a enbic $\rho^{3}$. The plane $\boldsymbol{\Phi}_{1}$ passing through $F_{1}$ and $s$ forms with the ruled surface $\Phi_{1}{ }^{3}$, deternined by $\sigma^{3}, F_{2}$ and $F_{3}$, a $\boldsymbol{\Phi}_{1}{ }^{3}$. Any other figure of [ $\left.\boldsymbol{\Phi}^{3}\right]$ intersects $\boldsymbol{T}_{1}{ }^{\text {a }}$ along a conic $\varrho_{1}{ }^{2}$ in the plane $\boldsymbol{\Phi}_{1}$, passing through $F_{1}$ and the intersections $S_{1}\left({ }^{(k)}\right.$ of $\sigma^{3}$, and a twisted curve ${\omega_{1}}^{\prime}$ intersecting $\sigma^{2}$ in five points $C_{1}{ }^{\prime}, C_{1}{ }^{\prime}$, which are determined by $\Phi_{2}{ }^{2}$; it passes of course through $F_{2}$ and $F_{3}$.

To the curves $\boldsymbol{o}_{1}{ }^{3}$ belong two degenerate figures each formed by the bisecant of $\sigma^{3}$ out of one of the points $C$, and the conic $\rho_{1}{ }^{2}$, in which $\Phi_{1}{ }^{3}$ is intersected by the plane, that connects the points $F_{3}$ and $F_{3}$ with the other point $C$. Apparently $\varphi_{2}{ }^{2}$ and the corresponding $\varrho_{1}{ }^{2}$ form a degenerate curve $\varrho^{4}$.

The three degenerate conics $\rho_{1}{ }^{2}$ as well determine degenérate curves $0^{4}$. For the straight line $S_{1}{ }^{\prime} S_{1}^{\prime \prime}$ is a bisecant $b$; hence the line $F_{1} S_{1}{ }^{\prime \prime \prime}$ forms with the corresponding $\rho_{1}{ }^{3}$ a degenerate figure $\varphi^{4}$.
3. To the net $\left[\boldsymbol{\Phi}^{3}\right]$ belongs the surface $\Sigma^{3}$, which has a node in a point $S$ of $\sigma^{3}$. This nodal surface determines with any other surface of the net a $\rho^{5}$, intersecting $\sigma^{3}$ in $S$, is therefore the locus of the $e^{5}$ passing through the singular point $S$.

The surfaces $\Sigma_{1}{ }^{3}$ and $\Sigma_{2}{ }^{3}$ have $s, \sigma^{3}$ and a $\rho^{3}$ in common, consequently one $\varrho^{5}$ passes through two points $S_{1}, S_{2}$ of $\sigma^{3}$. The groups of eight points, which the curves of the congruence determine on $\sigma^{3}$ form therefore an involution of the second rank. From this ensues that $\sigma^{3}$ 'is osculated by 18 curves $\rho^{5}$, and contains 21 pairs $S_{1}, S_{2}$ through which $\infty^{1}$ curves $\varrho^{5}$ pass. So there are 21 surfaces $\boldsymbol{T}^{3}$ each possessing two nodes lying on ' $\sigma^{3}$.

A straight line passing through the vertex $S$ of the monoid $\Sigma^{8}$ inter-
Rroceedings Royal Acad, Amsterdam، Vol, XVH.
sects the latter moreover in a point $P$ and the plane $\varphi$ passing through $F_{1}, F_{2}, F_{3}$ in a point $P^{\prime}$, which we shall consider as an image of $P$. As one $\rho^{5}$ passes through any point $P$, the curves of the congruence lying on $\boldsymbol{\Sigma}^{3}$ are represented by a pencil of rational curves $\mu^{4}$ : Every $\varphi^{4}$ has in common with the intersection $\psi^{3}$ of $\Sigma^{3}$ the five points, in which the corresponding $\dot{\rho}^{b}$ intersects the plane $p$; the remaining seven intersections of $p^{3}$ with $p^{4}$ are base-points of the pencil $\left(\varphi^{4}\right)$. To them belong the points $F_{1}, F_{2}, F_{3}$; the remaining four are intersections of four straight lines lying on $\Sigma^{3}$. One of them is intersected by every $\rho^{5}$ in $S$ and in a point $P$, is therefore a singular bisecant $p$ of the congruence; the involution which the $\infty^{1}$ curves $\varrho^{5}$ determine on it, is parabolic; so we might call $p$ a parabolic bisecant. The remaining three straight lines $d_{1}, d_{2}, d_{3}$ passing through $S$ are common trisecants of the curves $\varrho^{5}$; on these singular trisecants as well the involution of the points of support is special, for each group contains the point $S$.

The monoid $\boldsymbol{\Sigma}^{3}$ contains moreover two straight lines -passing through $S$ viz. the two bisecants of $\sigma^{3}$ cutting $s$, being consequently. component parts of two $\rho^{5}$ degenerated into a straight line $b$ and a $\rho^{4}$.

The pencil ( $\mathscr{\varphi}^{4}$ ) hass three double base-points $D_{1}, D_{3}, D_{5}$ and four single base-points $E, F_{1}, F_{2}, F_{3}$; it contains six compound tigures: three figures consisting of a nodal $\varphi^{3}$ and a straight line and three pairs of conics.

Let us now first consider the figure formed by the straight line $D_{2} D_{3}$ and the $\mu^{3}$, which has a nodal point in $D_{1}$ and passes through the remaining six base-points. It is the image of a figure consisting of a bisecant $b$ and a rational curve $\rho^{4}$; for the plane passing through $d_{2}$ and $d_{3}$ has only one straight line in common with $\Sigma^{3}$ so that $D_{2} D_{3}$ cannot be the image of a conic passing through $S$. Consequently there lie on $\Sigma^{3}$ three straight lines $b$ not passing through $S$, and therefore three curves ( $^{4}$ passing through $S$.

The conic passing through $D_{1}, D_{2}, D_{3}, E, F_{1}$ is the image of the conic $\rho^{2}$ which the plane ( $F_{1} s$ ) has in common with $\Sigma^{3}$; the conic to be associated to her passing through $D_{1}, D_{2}, D_{3}, F_{2}, F_{3}$ is the image of the $\varrho^{3}$ forming with $\rho^{2}$ a curve of the congruence [ $\rho^{5}$ ]. There are apparently there figures $\left(\rho^{3}, \rho^{2}\right)$ on $\Sigma^{3}$.
4. The curves $\rho^{5}$, meeting $s$ in a point $S^{*}$ lie on the nodal surface $\boldsymbol{J}^{3}$, which has $S^{*}$ as node. The monoids $\sum^{*{ }^{3}}$ belonging to two points of $s$, hare one $\rho^{5}$ in common; so the groups of four points which the $\rho^{6}$ have in common with $s$ form a $I_{2}{ }^{4}$. There are consequently six $\rho^{5}$ which osculate $s$, and three binodal surfaces $\boldsymbol{\Phi}^{3}$ which
have their nodes on 3 , consequently contain $\infty^{1}$ curves $\rho^{\dot{5}}$, intersecting $s$ in the same two points.

The $\rho^{5}$ of the monoid $\Sigma^{\boldsymbol{T}^{3}}$ are represented on the plane $\varphi \equiv F_{1} F_{2} F_{3}$ by a pencil of $\varphi^{4}$, which have the intersection $D$ of $s$ as triple point and pass through $\vec{l}_{1}, F_{2}, F_{3}$. The remaining base-points $E_{1}$, $E_{2}, E_{3}, E_{4}$ of that pencil lie in the intersections of straight lines $p_{k}$ of the monoid, which lines meet in $S^{*}$ and apparently are parabolic singular bisecants. The sixth straight line of the monoid passing through $S^{*}$ is the bisecant $b$ of $\sigma^{3}$, consequently part of a degenerate $\varrho^{5}$.

The straight line $D F_{2}$ is the image of the conic $\rho_{1}{ }^{3}$, in which the monoid is moreover intersected by the plane ( $s F_{2}$ ); the nodal $\rho^{3}$ completing it into a $\rho^{1}$ represents the cubic $\rho^{3}$, belonging to $\rho_{1}{ }^{2}$. So three figures ( $\varphi^{3}, \varrho^{2}$ ) lie on $\Sigma^{* 3}$.

The straight line $D E_{1}$ forms with the nodal cubic passing through $E_{2}, E_{3}, E_{4}, F_{1}, F_{2}, F_{3}$ and twice through $D$, the image of a degenerate $\rho^{5}$, consisting of the straight line $b$ in the plane $\left(s p_{1}\right)$ and a rational $\varrho^{4}$ passing through $S^{*}$. The monoid $\Sigma^{* 3}$ too contains therefore five figures ( $b, \rho^{4}$ ).
5. We can now determine the order of the locus of the rational curves $\rho^{4}$. It has $s$ as quadruple straight line and passes thrice through $\sigma^{3}(\$ 3)$. Its intersection with a $\sum^{*{ }^{* 3}}$ consists apart from these multiple lines of five curres $9^{4}$, is therefore of order 33. The rational curves $\varrho^{4}$ lie therefore on a surface of order eleven.

The section of this surface $\boldsymbol{\Phi}^{12}$ with the plane ( $F_{1} s$ ) consists of the quadruple straight line $s$, and parts of degenerate figures $\rho^{4}$. To it belong in the first place the three straight lines joining $F_{1}$ to the intersections $S_{1}^{(k)}$ of $\sigma^{3}(\$ 2)$; the remaining section is formed by the two $\rho_{1}{ }^{2}$ belonging to the bisecants $b$ out of the points $C_{1}^{\prime}, C_{1}^{\prime \prime}\left(\delta^{\prime} 2\right)$. A straight line passing through $F_{1}$ intersects $\Phi^{11}$ four times on $s$ and has with each of the two conics $\boldsymbol{o}_{1}{ }^{2}$ a point of intersection not lying in $F_{1}$; so five intersections lie in $F_{1}$. The three fundamental points $F$ are therefore quintuple points of $\boldsymbol{P}^{11}$.

In order to determine the locus of the intersection $B$ of a $\rho^{4}$ with the bisecant $b$ coupled to it, we consider on $s$ the correspondence between ${ }^{\circ}$ its intersections with $b$ and $\rho^{4}$. Through any point $P$ passes one $b$; to it are associated the three points $Q$, which $\varrho^{4}$ has in common with $s$. In each point $Q, s$ is intersected by four curves ${ }^{4}$; hence four points $P$ are associated to $Q$. From this it appears that $s$ contains seven points $B$. A plane passing throngh $s$ contains three straight lines $b$, consequently three points $B$; so the
points $B$ lie on a curve $\beta^{10}$ with septuple secant $s$. In the samenway it appears that $\beta^{10}$ meets $\sigma^{3}$ in 15 points, The surfaces $\boldsymbol{\Phi}^{11 \cdot}$ and $(b)^{4}$ have in $s$ and $\sigma^{3}$ a section of order $4+3 \times 2 \times 3$; moreover they have $\beta^{10}$ in common. The remaining section of order 12 must consist of straight lines belonging to degenerate figures $\varrho^{\overline{5}}$, each composed of a $\rho^{3}$ and two straight lines $b$ intersecting it. From this it ensues that $\left[\rho^{5}\right]$ contains six figures consisting of a twisted cubic and two of its secants.

This result may also be formulated in this way: through three points $F_{k}$ pass 6 curves $9^{3}$ which intersect a given $\sigma^{3}$ four times and a straight line $s$ twice. Such a $\rho^{3}$ intersects the ruled surface $(b)^{4}$ in two points $B$ lying outside $s$ and $\sigma^{3}$; through these points pass the two straight lines $b$, completing $\rho^{3}$ into a $\rho^{6}$.
6. Any straight line $d$ having threc points in common with a $\varrho^{6}$ is a singular trisecant of the congruence. For through it passes one $\boldsymbol{D}^{3}$ and the remaining surfaces of the net intersect it in the triplets of an involution. From this it ensues that the trisecants of the $\rho^{5}$ form a congruence of order three, as a $\rho^{5}$ is intersected in each of its points by three trisecants. In $\$ 3$ it has been proved that any point $S$ of $\sigma^{3}$ also sends ont three straight lines $d$; on these singular trisecants, however, all the groups of the $I_{s}$ have the point $S$ in common.

Let $b$ be a bisecant of a $\rho^{5}$ intersecting $\sigma^{2}$. Through it passes one $\Phi^{3}$; the net therefore determines on $b$ an involution $I^{2}$, so that $b$ is a singular bisecant.

Through a point $P$ pass four straight lines $b$. For the curve $\varrho_{P}^{s}$, which can be laid through $P$ is projected out of $P$ by a coue $k^{4}$; the latter has in common with $\sigma^{3}$ the eight points in which $\varrho_{p}^{5}$ rests on $\sigma^{3}$. The remaining four intersections lie on edges of $k^{4}$, which have in common with $\varrho_{P}^{5}$ two points not lying on $\sigma^{3}$, consequently are singular bisecants.

These four straight lines $b$ lie on the surface $\Pi$, which is the locus of the pairs of points, which the curves of $\left[\rho^{5}\right]$ have in common with their chords passing through the point $P, \Pi$ is apparently a surface of order six with' quadruple point $P$, the tangent cone of which coincides with $k^{4}$.

I7 ${ }^{6}$, contains' $s$ and $\sigma^{3}$, therefore has with an arbitrary $\varrho^{6}$ four points of $s$ and eiglt points of $\sigma^{7}$ in common; of the remaining 18 points of intersection 12 lie on the 6 chords, which $\boldsymbol{o}^{6}$ sends through , $P$, and 6 in the points $F$. Hence $\Pi^{s}$ has three nodes $F_{k}$, .

With the cone $\hbar^{4} \cdot \Pi^{9}$ has the curve $o P^{5}$ in common; the remaining section can only consist of straight lines. To it belong the three parabolic bisecants $P F_{k}$ and the four singular bisecants b. From this it ensues that the three trisecants $d$ which $\varrho P^{5}$ sends through $P$ are nodal lines of $\Pi^{8}$.

For a point $S$ of the singular curve $\sigma^{3}$ the surface $\Pi^{8}$ degenerates into the monoid $\Sigma^{3}$ and a cubic cone $l^{3}$, formed by singular bisecants $b$. The straight lines $b$ form therefore a congruence of order four, with singular curve $\sigma^{3}$, consequently of class nine.
7. The surface $A$ formed by the $\rho^{5}$. intersecting a straight line $l$, has the $\varrho^{5}$ intersecting $l$ twice as nuclal curve.

As $l$ intersects every monoid $\Sigma^{3}$ thrice, $s$ and $\sigma^{3}$ are triple lines on $A$. The section of $A$ with the plane ( $F_{1} s$ ) consists of the triple straight line $s$ and three conics $\rho_{1}{ }^{2}$; of these, one passes through the intersection of $l$, the other two are determined by the two curves $\varrho_{1}{ }^{9}$ resting on $l$. So $\boldsymbol{A}$ is a surface of order nine, with triple points in $F_{1}, F_{2}, F_{3}^{\prime}$.

On $\boldsymbol{A}^{2}$ lie 15 straight lines, 9 conics, 9 curves $\varrho^{3}$ and 15 rational curves, $\varrho^{4}$. For $l$ intersects 4 bisecants $b, 11$ curves $\varrho^{4}$; 3 conics and 6 curves $\varrho^{3}$.

A plane $\lambda$ passing through $l$ intersects $A^{3}$ along a curve $\lambda^{8}$; the latter has in common with $l$ the points, in which $l$ is intersected by the $\rho^{5}$, which bas $l$ as bisecant. In each of the remaining six points $\lambda$ is tonched by a $\rho^{5}$ of the congruence.

The locus of the points in which a plane $p$ is touched by curves $\rho^{5}$ is therefore a curve $\varphi^{0}$. It is the curve of coincidence of the
 $S^{*}, S_{1}, S_{3}, S_{3}$ of the singular lines $s . \sigma^{3}$ are apparently nodes of $\rho^{6}$.

With the surface $\Lambda^{n}$ belonging to an arbitrary straight line $l, q^{\prime \prime}$ has in those intersections $4 \times 3 \times 2$ points in common; in each of the remaining intersections $\varphi$ is touched by a $\rho^{5}$ resting on $l$.

The curves $\varrho^{5}$ touching $\varphi$ form therefore a surface $\boldsymbol{\Phi}^{30}$.
A monoid $\Sigma^{3}$ has in the points $S^{*}, S_{k} 4 \times 2$ points in common with $\rho^{0}$; on $\psi^{8}$ lie therefore the points of contact of 10 curves $\mathbf{o}^{5}$ ' of the monoid. From this it ensues that $s$ and $\sigma^{3}$ are decuple lines of $\boldsymbol{m}^{30}$. . With the curve $\boldsymbol{\psi}^{0}$, belonging to the plane $\boldsymbol{\psi}$, $\boldsymbol{\Phi}^{\mathrm{io}^{0}}$ has, in the four nodes of $\boldsymbol{\psi}^{\text {i }}, 4 \times 2 \times 10$ points in common; in each of the remaining intersections $\psi$ is touched by a $\rho^{5}$, which at the same time touches the plane $\varphi$. There are consequently 100 curves $\varrho^{6}$, touching two given planes.

The plane of has with $\boldsymbol{P}^{30}$, besides the curve of contact $\rho^{0}$ to be
counted twice, a curve $\varphi^{18}$ in common possessing four sextuple points in $S^{*}, S_{k}$. Apart from the multiple points, $\varphi^{6}$ and $\varphi^{18}$ have moreover $6 \times 18-4 \times 2 \times 6$ points in common; from this it ensues that each plane is osculated by thirty curves $\varrho^{5}$.

Mathematics. -- "Some particular bilinear congruences of twisted cubics." By Prof. Jan de Vries.
(Communicated in the meeting of March 27, 1915).
The bilinear congruences of twisted cubics $0^{3}$ may principally be brought to two groups. ${ }^{\text {i }}$ ) The congruences of the first group may be produced by two pencils of ruled quadrics, the bases of which have a straight line in common; the congruences of the second group consist of the base-curves of the pencils belonging to a net of cubic surfaces, which bave in common a fixed point and a twisted curve of order six and genus three. Reye's congruence formed by the $\rho^{3}$ passing through five given points $F_{k}$, belongs to both groups; it may be produced by two pencils of quadratic cones; the straight lines, connecting each of two points $H_{1}, F_{2}$ with each of the remaining four, are base-edges. We shall now consider some other particular cases of congruences of the first group, which may also be produced by two pencils of quadratic cones.

1. We consider the curves $\varrho^{3}$ passing through the fundamental points $F_{1}, F_{2}, F_{3}, F_{4}$ and having the lines $s_{1}$ (passing through $F_{1}$ ) and $s_{2}$ (passing through $F_{2}$ ) as chords. Each $\Downarrow^{3}$ is the partial intersection of a quadratic cone passing through the lines ( $s_{1}, F_{1} F_{2}, F_{1} F_{3}, F_{1} F_{4}$ ); $\left(s_{2}, F_{3} F_{1}, F_{2} F_{3}, F_{2} F_{4}^{\prime}\right)$; the congruence is consequently bilinear. Apparently $s_{1}$ and $s_{2}$ are singular bisecants. Any point $S_{1}$ of $s_{1}$ is singular; the $\Downarrow^{3}$ passing through $S_{1}$ lie on the cone of the second pencil passing through $S_{1}$. Consequently $s_{1}$, as well as $s_{2}$, is a singular straight line of order two.

The figures of the congruence consisting of a straight line $d$ and a conic $\boldsymbol{\sigma}^{2}$, may be brought to four groups.
A. The straight line $d_{12} \equiv F_{1} F_{2}$, may be combined with any $\delta^{2}$ of the system of conics passing through $F_{3}$ and $F_{4}$ and resting on

[^1]
[^0]:    り) Two other particular nets I have considered in two communications placed in volume XVI (p. 733 and p. 1186) of these "Proceedings". They determine bilinear congruences of twisted quartics (1st and 2nd species).

[^1]:    1) Veneron, Rendiconti del Circolo matematico di Palermo, tomo XVI, 209229. In a short communication in vol. XXXVII, 279, of the Rendiconti del Ist. Lombardo, Veneroni has added to these trio main types a third which by the way may be considered as a limit case of the first type. This congruence may be produced by a pencil of quadrics aud a pencil of quartic surfaces, one surface of which is composed of two quadrics of the first pencil. The bases of the pencils have a straight line in common, which -is nodal line-for the second-pencil,
