In order to determine the surface $\Sigma^{n+1}$ belonging to the stranght line whicì joins the points $Y$ and $Z$, one has to eliminale $a, \beta, \gamma, \delta$ out of $\Sigma \alpha y_{1}=0, \Sigma \alpha z_{1}=0, \Sigma \alpha x_{1}=0$ and $\Sigma \alpha \alpha_{x}^{n}=0$; then one finds

$$
y_{1} \quad z_{1} \quad x_{1} \cdot a_{x}^{n} \mid=0
$$

while the straight line $\Gamma Z$ is indicated by

$$
\left\|y_{k} \quad z_{k} \quad x_{k}\right\|=0 .
$$

Through the point $X$ pass the axes of the points $Y$, for which we have

$$
\left|\begin{array}{ccc}
y_{1} & a_{y}^{n} & x_{1} \\
y_{2} & b_{y}^{n} & x_{2} \\
y_{3} & c_{y}^{n} & x_{3}
\end{array}\right|=0 \text { and }\left|\begin{array}{ccc}
y_{2} & b_{y}^{n} & x_{2} \\
y_{3} & c_{y}^{n} & x_{3} \\
y_{4} & d_{y}^{n} & x_{4}
\end{array}\right|=0
$$

These surfaces of order $(n+1)$ have the curve

$$
\left\|\begin{array}{ccc}
y_{3} & b_{y}^{n} & x_{2} \\
y_{3} & c_{y}^{n} & x_{3}
\end{array}\right\|=0
$$

in common, which is of order $n$, but is not situated on the two other surfaces of order $(n+1)$, which are indicated by

$$
\left\|\begin{array}{lll}
y_{1} & a_{y}^{n} & x_{1}
\end{array}\right\|=0
$$

The last mentioned relations determine therefore a curve of order $\left(n^{2}+n+1\right)$ as locus of the points $Y$. From this ensues again that the axes form a complex of rays of order $n(n+1)$.

Mathematics. - "A bilinear congruence of twisted quartics of the first species." By Prof. Jan de Vriss.

1. As we know, we distinguish with congruences of algebraic twisted curves two characteristic numbers, called order and cluss.

The order indicates how many curves pass through an arbitrary point, the class the number of curves which have an arbitrarily chosen straight line as a bisecant If both numbers are one the congruence is called bilinear. In volume XVI of the Rend. del Circ. mat. di Palermo (p. 210) E. Venkroni has proved that there exist principally two kinds of bilinear congruences of twisted cubics. An analogous inquiry concerning congruences of twisted quartics of the first species, $\varrho^{4}$, has not been made till now. ${ }^{1}$ )

[^0]In a communication which appeared in Volume XIV of these Proceediugs, I have ( p .255 ) considered the bilinear congruence [ $9^{4}$ ], which arises if the quadrics of two pencils are made to intersect. ${ }^{1}$ )

It is not difficult to understand that no bilinear congruences of curves of a higher order can be produced by two pencils of surfaces. For, if these pencils are of the degrees $m$ and $n$, they intersect an arbitrary line in two involutions of the degrees $m$ and $n$ and these have in common $k=(m-1)(n-1)$ pairs; so we find a congruence $\left[\rho^{m n}\right.$ ] of the tirst order, and the class ( $m-1$ ) $(n-1)$; only for $m=n=2$ we find $k=1$.
2. In order to arrive at another group of bilinear congruences, I consider a net of cubic surfaces [ $\mathscr{\Phi}^{3}$ ]. Through an arbitrayy point $P$ pass $\infty^{1}$ surfaces $\boldsymbol{\Phi}^{3}$, which form a pencil included in the net, of which pencil the base curve in the general case will be a twisted curve $\varrho^{\circ}$ of genus 10. All the curves $0^{\circ}$ included in the net consequently form a congruence of order one. On an arbitrary line the net determines a cubic involution of the second rank; the latter possesses as we know a neutral pair $N_{1}, N_{2}$; all the $\varrho^{9}$ through $N_{1}$ pass through $N_{2}$ as well, consequently the congruence is also of the first class, therefore bilinear.

If all the $\Phi^{3}$ have a curve in common, the curves $\rho^{2}$ degenerate into an invariable and a variable part, and a bilinear congruence of curves of a lower order is found. We shall now consider the rase in which we have to do with a congruence [ $\left.\rho^{\prime}\right]^{\prime}$.
3. Let $\rho^{6}$ be a twisted curve of order five, and let the gerus be 2, so the remaining section of a $\boldsymbol{\Phi}^{3}$ and a $\boldsymbol{\Phi}^{2}$, which have a straight line in common. Any surface $\boldsymbol{P}^{5}$ passing through 14 points of $\varrho^{5}$ contains this curve ${ }^{2}$ ); consequently the $\Phi^{3}$ passing through $\varrho^{5}$, and three arbitrarily chosen points $H_{1}, H_{2}, H_{3}$, form a net. Two of these surfaces have besides $\varrho^{6}$, a $\varrho^{4}$ of the $1^{\text {st }}$ species in common, which intersects $\rho^{5}$ in eight points ${ }^{0}$ ). With a third $\Phi^{3}, 6^{4}$ has 12 points in common, of which 8 lie on $\rho^{5}$, the other four, and to them belong of course $H_{1}, H_{2}$ and $H_{3}$ lie apparently on all $\Phi^{3}$, therefore on all $o^{4}$.

[^1]Here we have consequently a bilinear congrumene [ $9^{4}$ ] with four carcinal points $H_{k}$ and a singular curve $\varphi^{5}$; i.e. all $\varphi^{4}$ pass through the four cardinal points and rest in 8 points on $\left.e^{51}\right)$.
4. Let $t$ be a trisecant of $\varrho^{5}$; the pencil of net surfaces determined by a point of $t$ has for base the complex of $p^{5}, t$ and a plane cubic $\gamma^{3}$, which bas a point $T$ with $t$ in common, and 5 points with $\varrho^{5}$. This $\gamma^{3}$ must contain the four cardinal points $H$; cinsequently the cardinal points are situated in a plane $\varphi$.

Any curve $\gamma^{3}$ connects the 4 cardinal points and the 5 points $R_{k}$, in which $\varrho^{5}$ cuts the plane $\varphi$, with the intersecting point $T$ of the trisecant belonging to it. As the trisecants form the quadratic ruled surface $\Phi^{2}$, on which $\rho^{6}$ lies, the points $R$, together with $T$ may be connected by a conic $\tau^{2}$.

The curves $\gamma^{3}$ form a pencil with base ( $R_{k}, H_{l k}$ ); any $\gamma^{3}$ intersects $\boldsymbol{\tau}^{2}$ in the point $T$, through which the straight line $t$ passes, which, considered together with $\gamma^{3}$ belongs to the congruence $\left.\left[\rho^{4}\right]{ }^{9}\right)$.

The locus of the degenerate figures ( $\gamma^{3}+t$ ) is apparently the complex of $\Phi^{2}$ and $\varphi$, and consequently belongs to the net $\left[\phi^{3}\right]$.
5. Let $b$ be one of the four bisecants of $\rho^{6}$, which pass through the cardinal point $H_{l}$. All the $\Phi^{3}$ which contain $b$, have moreover a $\varrho^{3}$ in common, which has $b$ as bisecant and rests in 6 points on $\varphi^{5}$.

Consequently there are sixteen figures ( $\rho^{2}+b$ ) in [ $\left.\rho^{4}\right]$.
A third group of complex figures is formed by pairs of conics $\left(\alpha^{2}, \beta^{2}\right)$. Let $a^{2}$ be a conic passing through $H_{1}, H_{2}$, intersecting $\rho^{5}$ in 4 points, the $\boldsymbol{\Phi}^{3}$ passing through $a^{2}$ and $\varrho^{5}$ have an other conic $\bar{p}^{2}$ in common, which intersects $\alpha^{2}$ in 2 points, $\varrho^{6}$ in 4 points and passes through $H_{3}, H_{4}$

The number of as we deduce using the law of permanency of the number. We replace $\rho^{5}$ by the complex of a $\sigma^{3}$ and a $\sigma^{2}$, which have three points in common; through a point $P$ pass consequently 3 straight lines, which rest on $\sigma^{3}$ and $\sigma^{2}$; with the bisecant of $\sigma^{3}$ they form the 4 straight lines which replace the 4 bisecants of $\rho^{5}$; consequently ( $\sigma^{3}+\sigma^{3}$ ) is to be considered as a degeneration of $v^{5}$. In any plane passing through $H_{1}$ and $H_{2}$ lies a conice $\varphi^{2}$ connecting these points with 3 points of $\sigma^{3}$; as the straight line $H_{1} H_{2}$ cannot

[^2]apparently be a part of a degenerate $\varphi^{3}$, the $\varphi^{2}$ form a quadric. This is cut by $\sigma^{2}$ in 4 points; among them are the 3 common points of $\sigma^{3}$ and $\sigma^{2}$; through the fourth intersecting point passes a $\varphi^{2}$; which has four points in common with the figure ( $\sigma^{3}+\sigma^{2}$ ).

From this we conclude that one conic $a^{2}$ can be drawn through $H_{1}$ and $H_{2}$. As each $\mu^{2}$ is coupled with a $\beta^{2}$ (which passes in that case through $B_{3}$ and $H_{4}$ ), $\left[\rho^{4}\right]$ contains three figures $\left(\alpha^{2}+\beta^{2}\right)$.
6. Through a point $S$ of the singular curve $\varphi^{3}$ pass $\infty^{2}$ curves $\varrho^{4}$. They cut the plane $\varphi$ in the points $H$. To this sysiem of $\varphi^{1}$ belongs, however, also the figure consisting of the trisecant $t$ passing through $S$ and a $\gamma^{3}$ lying in $\varphi$. From this ensues that the locus of the $\rho^{4}$ meeting in $S$, is a cubic surface $\Sigma^{3}$, passing through $\rho^{5}$ and the points $H$, and consequently belongs to the net [ $\boldsymbol{\Phi}^{3}$ ].

An arbitrary line passing through $S$, is a bisecant of one $\varrho^{4}$, and so intersects $\Sigma^{3}$, apart from $S$ in one point. Consequently $\Sigma^{3}$ has a double point in $S$. Through $S$ pass 6 straight lines of $\Sigma^{3}$, one of them is of course the $t$ mentioned before; each of the remaining 5 is a bisecant $p$ of $\infty^{1}$ curves $\varrho^{4}$, so a singular bisecant.

All the $\varrho^{4}$ intersecting $p$ twice pass through $S$; so they determine on $p$ a parabolic involution, of which all pairs have the point $S$ in common; we shall call $p$ a singular bisecant of the first species.

Through each point of $\varrho^{s}$ pass therefore five singular bisecants of the first species.

Any line $h$ passing through a cardinal point $H$ is as 'well a singular bisecant of the first species.

The monoids $\Sigma^{3}$ having two points of $\rho^{5}$ as double points, intersect apart from $\varrho^{5}$ in a $\varrho^{4}$. Through any two points $S$ passes therefore only one curve of the congruence.
7. Let $q$ be a bisecant of a $6^{5}$, and at the same time a secant of $\varrho^{4}$. The surface $\Phi^{3}$ passing through $\varrho^{5}$ and $\varrho^{4}$ and a point of $q$ contains $q$, and belongs to the net [ $\boldsymbol{\Phi}^{3}$ ]. Consequently all $\boldsymbol{\Phi}^{3}$ passing through a point $Q$ of $q$ will cut this straight line moreover in a second point $Q^{\prime}$. Consequently $q$ is a bisecant of $\infty^{1}$ curves $\rho^{4}$, and the pairs of the intersections $Q, Q^{\prime}$ form an involution. We call $q$ a singuldar bisecant of the second species.

In order to find the number of lines $q$ that pass through a point $P$, we consider the cubic cone $k^{3}$, which out of $P$ projects the $\rho^{4}$ containing $P$, and the cone $k^{5}$ which has $P$ as vertex and $\varrho^{5}$ as curve of direction. To the 15 cominon generatrices belong the lines drawn to the eight intersecting points of $\varphi^{4}$ and $\rho^{6}$. The remaining

7 are bisecants of $\varrho^{4}$ intersecting $\varrho^{5}$, therefore lines $q$. Consequently the lines $q$ form a congruence of order seven.

We can also arrive at this result in another way. A staaight line passing through $P$ is generally speaking, a bisecant of one $\rho^{4}$; we call $R, R^{\prime \prime}$ its intersections with $\varrho^{4}$ and consider the surface $\pi$, which is the locus of the pairs $R, R^{\prime}$. On any generatrix of the cone $l^{3}$ one of those points lies in $P$, hence $\boldsymbol{x}$ has in $P$ a triple point with $h^{3}$ as tangent cone; $\pi$ is consequently a surface of order 5 . It passes through $\varrho^{6}$, and has nodes in the four cardinal points. For an arbitrary $\rho^{4}$ has in common with $\pi$ the intersections with the bisecants which it sends through $P$, and in 8 points of $\rho^{5}$, so twice in each point $H$.
Now $\pi^{5}$ and $k^{3}$ have in common the $\varrho^{4}$ which passes through $P$; further they can, by reason of the definition of $\boldsymbol{\pi}$, only have lines in common which contain $\infty^{1}$ pairs $R, R^{\prime}$ each. Therefore eleven singular lisecants pass through $P$. To these the four straight lines $h_{k}=P H_{k}$ belong; for through any point of $P H_{k}$ passes a $\varrho^{4}$, which meets this straight line again in the cardinal point $H_{k}$, so that $P H_{k}$ is a singular straight line of the first species (which, however, does not rest on $\varrho^{5}$, and consequently may not be interchanged with a straight line $p$ ). The remaining 7 singular bisecants passing through $P$ are therefore straight lines $q$.
For a point $S$ of $\rho^{5}$ the surface $\boldsymbol{\pi}^{5}$ degenerates, and consists of the monoid $\Phi^{3}$ with node $S$ and a quadratic cone, formed by the straight lines $q$, which intersect $\rho^{5}$ in $S$.

In an arbitrary plane lie five points of $\rho^{5}$, consequently 10 straight lines $q$; they belong therefore to a congruence of rays of class ten.

The singular bisecants of the second species form a congruence (7, 10), which has $p^{5}$ as a singular curve.

The section of $\boldsymbol{x}^{5}$ with a plane passing through $P$ is a curve with a triple point, consequently of class 14, of its tangents 8 pass through $P$. Therefore the tangents of the curres $\varrho^{4}$ form a complex of order eiglt.
8. The $0^{4}$ which [intorsect a given line $l$, form a surface $A$, of which we intend to determine the order $\boldsymbol{x}$. Any monoid $\boldsymbol{\Phi}^{3}$ contains three $\varrho^{4}$, which intersect $l$, and rest in the vertex $S$ on $\rho^{5}$; consequently $\rho^{5}$ is a triple curve of $a$.

The surfaces $A, A^{\prime}$ belonging to two lines $l, l^{\prime}$ have, besides the threefold curve $\varrho^{5}$ only the $x$ curves $\varrho^{4}$ in common, resting on $l$ and $l^{\prime}$. So we have the relation $x^{2}=4 x+3^{2} .5$, hence $x=9$.

On $A^{9}$ lies one trisecant $l$; for the curve $\gamma^{3}$, which intersects $l$,
determines on $\tau^{2}$ the point $T$ of the trisecant with which it forms a degenerate $\varrho^{4}(\$ 4)$.
The curve $\varrho^{4} l$, which has $l$ as a bisecant belongs to two points. of $l$, and is consequently a twofold curve of $\Lambda^{3}$.
The locus of the $\varrho^{4}$ intersected by $l$ is-therefore a surface of order nine wilh a twofold curve $\varrho^{4}{ }_{l}$, a triple curve $\varrho^{5}$ and two straight lines $l$ and $t$.
9. A plane through $l$ intersects $\Lambda^{3}$ in a curve $\lambda^{8}$; the latter has the two intersections of $\varrho^{4} l$ and six points $R$ in common with $l$; in each point $R, 2$ is touched by a $\varrho^{4}$.
The points in which a plane is touched by curres $\varrho^{4}$ lie therefore on a curve $\gamma^{\circ}$; it is the culrve of coincidences of the quadruple involution $Q^{4}$, in which the plane 2 is intersected by the congruences $\left[0^{1}\right]$.

The five intersections $S_{l}$ of $\varrho^{5}$ with $\lambda$ are apparently singular points of $Q^{4}$; to $S_{k}$ are namely conjugated $\infty^{1}$ triplets of points, lying on the cubic curve $\sigma^{3} k$, with double point $S_{k}$, in which the monoid $\Phi^{3}$ (with vertex $S_{k}$ ) is intersected by $\lambda$. In $S_{k} 2$ is therefore touched by two $\stackrel{\wedge}{4}^{4}$; the curve of coincidences $\gamma^{6}$ has consequently nodes in each of the five points $S_{k}$, and in $S_{k}$ the same tangents as $\sigma_{k}{ }^{3}$.

Any point $D$ of the conic $\boldsymbol{\sigma}^{2}$ through $S_{k}$ is the intersection of a trisecant $t$, consequently determines a quadruple, of which the remaining three points are produced by the intersection of the curve $\gamma^{8}$ coupled with $t$. On the section $f$ of $\varphi$ we have therefore a cubic involution $F^{3}$, of which the groups are completed into quadruples of $Q^{4}$ by the points $D$. It is evident that $Q^{4}$, as long as $\lambda$ remains an arhitrary plane, cannot possess any other collinear triplets.

In each of the points of intersection $T_{1}, T_{2}$ of $f$ with $\tau^{2}(\$ 4)$ a $t$ is cat by a $\gamma^{3}$, consequently these points are coincidences of the $Q^{4}$. The remaining coincidences, lying on $f$, belong to the involution $F^{3}$, from this appears again that the order of the curve of coincidences is six.

As the singular point $S_{1}$ lies on $\delta^{2}$ and therefore may be considered as a point $D$, the curve $\sigma_{1}{ }^{3}$ is intersected by $f$ in a triplet of the cubic involution $I_{1}{ }^{3}$, of which the groups are completed into quadruples of $Q^{4}$ by $S_{1}$. As $I_{1}{ }^{3}$ cannot possess a second collinear triplet, it is not a central involution; so it can be determined in $\infty^{1}$ ways by a pencil of conics of which the base points are $S_{1}$, an arbitrary point of $\sigma_{1}{ }^{3}$, and moreover two points of the line $f$.
10. Any coincidence of the $Q^{4}$ is completed into a quadruple by two complementary points. The locus of those points which we shall call the complementary curve has apparently quadruple points in $S_{k}$; for $I_{k}{ }^{3}$ has four coincidences. Of the four coincidences of $F^{3}$, four of the complementary points lie on $d^{2}$; with this conic the curve $\boldsymbol{d}$ has therefore $4+5 \times 4=24$ points in common. Consequently the complementary curve is of order 12.

The curves $\rho^{4}$, which touch the plane 2. in the points of the curve of coincidences $\gamma^{6}$, intersect $\lambda$ moreover on the complementary curve $d^{12}$; so they form a surface of order 24 , which passes eight times through the curve $6^{6}$.

This surface is intersected by a plane $\lambda^{\prime}$ along a curve of order 24 with 5 octuple points $S_{h}$. As the curve of coincidences $\gamma^{\prime 6}$ lying in $\lambda^{\prime}$ has double points in $S_{k}$ the two curves outside $S_{k}$ have $24 \times 6-5 \times 8 \times 2=64$ points in common. Consequently there are 64 curves $\varrho^{4}$, touching two given planes.

The surface $\boldsymbol{\Lambda}^{9}$ belonging to the straight line $l$ intersects an arbitrary plane $P$ along a curve $\mathscr{P}^{p}$, which has 5 triple points on $\varphi^{6}$. As the curve of coincidences $\varphi^{6}$ lying in $\varphi$ has 5 modes on $\rho^{6}$, it intersects i $^{2}$ moreover in $9 \times 6-5 \times 3 \times 2=24$ points. From this appears once more that the curves $\left(1^{4}\right.$, which touch a given plane, form a surface of order 24. At the same time, the fact that the complementary curve is of order 12, is confirmed.

Chemistry. - "Equilibria in ternary systems". XII. By Prof. Schreinemakers.

We have seen in the previous communication that the salurationcurve under its own vapour-pressure of the temperature $T_{H}$ (the point of maximumtemperature of the binary system $F+L+G$ ) is either a point [fig. $5(\mathrm{XI})$ ] or a curve [fig. $6(\mathrm{XI})$ ]. We shall now examine this case more in detail.

If we calculate $\frac{d y}{d x}$ for this curve in the point $H$ from (6) and (7) (XI), then we find an infinitely great value. The curve going through $H$ in fig. 6 (XI) and the curve disappearing in $H$ of figure 5 (XI) come in contact, therefore, in $H$ with the side $B C$. Now we take a temperature somewhat lower than $T_{H}$. The saturationcurve under its own vapour-pressure terminates then in two points $n$ and $h$ situated on different sides of and very close to $H$. [ $n$ and $h$ in fig. 4-6 (XI) may be imagined very close to $H$. $\rceil$ As the saturationcurve
