Mathematics. - "On the correspondence of the pairs of points separated harmonically by a twisted quartic curve." By Prof. Jan de Vries.
(Communicated in the meeting of November 30, 1912).
§ 1. We indicate by $P$ and $Q$ two points, lying on a chord of a twisted quartic curve of the first kind, separated harmonically by this curve $\varrho^{4}$. As any point $P$ lies generally on two chords, in the correspondence $(P, Q)$ to any point $P$ wo points $Q$ are conjugated.

If $F$ moves along a line $l, Q$ describes a curve $\lambda^{\circ}$ of order six. For any plane $\Delta$ through $l$ cuts $Q^{4}$ in forr points $S_{k}$ and contains therefore six points $Q_{k l}$, where $Q_{k l}$ lies on a chord $S_{k} S_{l}$ and is harmonically conjugated to the points $P_{k l}$ common to that chord and $l$. If $l$ is an arbitrary line, $Q$ never lies on $l$ when $A$ rotates about $l$.

The line $Q_{13} Q_{23}$ is separated harmonically from $l$ by $P_{12} S_{3}$ and $S_{1} S_{2}$. By assuming a position for $A$ in which $S_{1}$ and $S_{2}$ coincide with $Q_{12}$ we find for $Q_{13} Q_{23}$ a tangent of $\lambda^{6}$ separated harmonically from $l$ by $P_{12} S_{1}$ and $P_{12} S_{3}$, whilst an other tangent of $i^{5}$ takes the place of $Q_{14} Q_{24}$. So each of the eight tangential planes of $\rho^{1}$ contains two tangents of $\lambda^{6}$; so the rank of this curve is sixteen.

Moreover we find that $\lambda^{\circ}$ has eight points in commion wilh $\rho^{\prime}$.
§2. The line $p$ connecting the two points $Q, Q^{\prime}$ conjugated to $P$ describes a regulus $A^{2}$ if $P$ moves along $l$. For $p$ is the polar line of $P$ with respect to $g^{i}$, i. e. the intersection of the polar planes of $P$ with respect to any two quadratic surfaces through $Q^{4}$, and these polar planes describe two projective pencils.
-Let us now consider one of the two lines $p$ cutting $l$. The corresponding point $P$ bears two chords $S_{1} S_{2}$ and $S_{3} S_{4}$ lying in the plane $A=l p$. The points $Q_{12}$ and $Q_{31}$ lie on $\mu$, the points $Q_{13}, Q_{23}$, $Q_{11}, Q_{24}$ lie on a line $m$ through $P$ harmonically separated from $l$ by the chords $S_{1} S_{2}$ and $S_{3} S_{4}$. As $\lambda^{4}$ lies on the regulus $A^{2}, m$ is a line of $A^{2}$. Any tangential plane of $A^{3}$ contains thereforc a quadrisecant of $\lambda^{6}$ and beth the reguli of $A^{2}$ are arranged by $\lambda^{6} \mathrm{in}$ a correspondence $(2,4)$. Evidently the quadrisecanis $q$ are the polar lines of $l$ with respect to the quadratic surfaces ihrough $\varphi^{1}$.
§3. If we assume for $l$ a chord of $6^{4}$, the locus of $Q$ breaks up into four parts, i. e. the chord $l$ itself, the tangents $r$ and $r^{\prime}$ in the points $R, R^{\prime}$ common to $l$ and $凶^{4}$, and a twisted culvic $\lambda^{3}$. The polar line $p$ now connects a point $Q$ of I with the point $Q^{\prime}$ of the second chord $k$ passing throngh $P$. This line describes a regulus
having with $A^{2}$ the line $l$ in common. So the locus of $Q^{\prime}=k$ is a curve $\lambda^{3}$ throngh $l_{i}$ and $R^{\prime}$, as $l$ is to have two points in common wilh it and $R$ and $R^{\prime}$ correspond amongst other points with themselves; the curves $\lambda^{3}$ and $\varrho^{4}$ have four more points in common.
$\$ 4$. If $l$ is a misecant of $\rho^{1}$ in $R$, the locus ( $Q$ ) degenerates into the tangent $r$ and $a i^{5}$. Any plane through $l$ contains besides $R$ three points $Q$; of these two must be combined with $R$, if the plane contains the tangent $r$. The quadrisccants $q$ of $l$ become here trisecants; for $r$ rests on each of the polar lines $q$ of $l(\$ 2)$. The plane $q$ tonches $o^{4}$ in $R$ and contains therefore two points $Q$ united in $R$. In relation with the results obtained we conclude from this that by the correspondence ( $P, Q$ ) to a unisecant of $a^{4}$ a twisted curve of order fice is conjugated having a node in the point common to the unisecimt and $\rho^{4}$, the nodal tangents lying in the plane $l$.

So the curve is of rank ten. Through $l$ pass six common tangential planes of $\rho^{4}$ and $\lambda^{5}$.
$\$ 5$. The vertices $T_{k}$ of the four quadratric cones containing $g^{\prime}$ are singular points of the correspondence ( $l, Q$ ). For $T_{1}$ bears $\infty^{1}$ chords and the corresponding points $Q$ lie on the conic $\tau_{1}$ common to the polar plane $\tau_{1}=T_{2} T_{3} T_{4}$ of $T_{1}$ and the quadratic cone with $T_{1}$ as vertex.

To the line $T_{1} T_{2}$ as locus of points $P$ correspond in the first place the two conics $\tau_{1}{ }^{2}$ and $\tau_{2}{ }^{\text {a }}$ and moreover the line $T_{3} T_{1}$ counted twice. For the points $S_{k}$ in any plane through $S_{1} S_{2}$ form a complete quadrangle of which $T_{1}$ and $T_{y}$ are diagonal points; in the third diagonal point $Q_{13}$ and $Q_{2}$, coincide, whilst of the remaining four points $Q$ two lie in $\boldsymbol{r}_{1}$ and two in $\tau_{2}$. So to any point of $T_{1}^{\prime} T_{2}$ correspond two points of $T_{3} T_{4}$ and inversely.

If $l$ contains the point $T_{1}$ only, the six points $Q$ lying in a plane ). through $l$ consist of two points in $\boldsymbol{r}_{1}$ and on $\boldsymbol{\tau}_{1}{ }^{2}$ and of four points lying on the line common to $\lambda$ and the polar plane of $l$ with respect to the cone projecting $\rho^{1}$ out of $T_{1}$. Then the curve $(Q)$ breaks up into the conic $x_{1}{ }^{2}$ and a plane carve $\lambda^{\prime}$. In the two tangential phanes of the cone passing through $l$ the two points $Q$ lying on $\tau_{1}{ }^{4}$ coincide with two of the remaining four in a point of intersection of $r_{1}{ }^{2}$ and $\lambda^{1}$ where the latter is touched liy the edge of contact.
$\$ 6$. Let us now consider the surface of the points $Q$ corresponding to the points $P$ of a plane $I$. If $S_{k}$ are the points common to $I I$ and $g^{4}$, the six lines $S_{L} S_{l}$ form the intersection of $I I$ with the
locus under discussion. So it is of order sir. As it contains at the same time the lines touching $\varrho^{4}$ in $S_{k}$, these points are nodal points. To the two points of $\tau_{2}{ }^{2}$ lying in $I I$ corresponl iwo points $Q$ coinciding with $T_{k}$, whilst to the point of II lying on $T_{k} T_{i}$ two points on $T_{m} T_{n}$ correspond. From this ensues that the four points $T$ have to be also nodes of $\Pi^{0}$.

So to a plane corresponds a surface of order six with eight nodes and ten lines.
§7. Let us now consider the correspondence between two points $P, Q$ separated harmonically by a twisted quartic curve of the second kind $\sigma^{4}$. As $P$ bears three chords of $\sigma^{4}$, it is conjugated to three points $Q$. To the points $P$ of a line $l$ correspond the points $Q$ of a twisted curve $\Lambda^{6}$; for each plane through $l$ contains six points $Q$.

The three points $Q$ corresponding to $P$ lie in the polar plane of $P$ with respect to the quadratic surface $H^{3}$ through $\sigma^{4}$. The plane $\Pi$ rotates about the polar line $l^{\prime}$ of $l$, if $P$ moves along $l$. So $l^{\prime}$ is a trisecant of $\lambda^{6}$.

The scroll of the chords of $\sigma^{4}$ cutting $l$ is of order nine; so nine of these chords also intersect $l^{\prime}$. To these nine belong the two trisecants of $\sigma^{4}$ cutting $l$, each of which represents three chords; they have to meet $l^{\prime}$, as they lie on the hyperboloid $H^{2}$ and are at the same time trisecants of $\lambda^{6}$. The remaining three chords cutting $l$ and $l^{\prime}$ determine the three points $Q$ on $l^{\prime}$.
§8. Each of the six tangential planes of $\sigma^{4}$ passing through $l$ contains a point and two tangents of.$^{6}$; so this curve is of rank twelve and rests in six points on $\sigma^{4}$. By $S_{l c}$ we represent the points of $\sigma^{4}$ lying in a plane drawn through $l$; the chord $b=S_{1} S_{2}$ is paired to the chord $b^{\prime}=S_{3} S_{4}$ and now we consider the correspondence between the points $P^{\prime}$ and $P^{\prime}$ in which $b$ and $b^{\prime}$ intersect l. As $P$ bears three chords we find a $(3,3)$. If $b$ and $b^{\prime}$ intersect $l$ in the same point $P$, only the third chord through $P$ furnishes a point $P^{\prime}$ not coinciding with $P$; from this ensues that the coincidencies of the ( 3,3 ) coincide by two in a double coincidency. So through $l$ three planes pass for which $b$ and $b^{\prime}$ intersect in $l$; the line $l$ separating $l$ harmonically from $b$ and $b^{\prime}$ then contains four out of the six points $Q$, the remaining two lying on $b$ and $b^{\prime}$.

So the curve $\lambda^{6}$ admits three quadrisecants.
§ 9 . Let $l$ be a chord of $\sigma^{4}$ and $S_{1}$ and $S_{2}$ the points it has in common with $0^{4}$. Through any point $P$ of $l$ pass two more chords
$b, b^{\prime}$ of $\sigma^{4}$. So the locus of the points $Q$ lies on a cubic scroll $A^{3}$ with double line $l$.
In the plane $b l$ two points $Q$ coincide in $S_{1}$, two other ones in $S_{2}$, whilst $Q_{12}$ lies in $l$ and $Q_{34}$ in $b$. If $P$ moves along $l, q=Q_{12} Q_{34}$ describes a cubic scroll $\boldsymbol{D}^{3}$ with double line $l$; for through $Q_{12}$ pass two lines $q, q^{\prime}$ to the points $Q_{34}$ of the chords $b, b^{\prime}$ concurring in the point $P$ corresponding to $Q_{12}$.

The scrolls $\Lambda^{3}, \boldsymbol{\Phi}^{3}$ have the trisecants $t_{1}, t_{2}$ of $\sigma^{4}$ passing through $S_{1}$ and $S_{2}$ in common. For if $P$ coincides with $S_{1}, t_{1}$ becomes a chord $b$ and, as $Q_{12}$ coincides then with $S_{1}$, at the same time a line $q$.

As $l$ is nodal line for both scrolls, these surfaces have still a twisted cubic $\lambda^{c}$ containing the points $Q_{34}$ in common. In the planes touching $\sigma^{4}$ in $S_{1}$ and $S_{2}$ the point $Q_{34}$ coincides with the point of contact; so $S_{1} S_{2}$ is a chord of $\lambda^{3}$. This curve intersects $\sigma^{4}$ in the two points the tangents of which intersect $S_{1} S_{2}$; it has for chords the single director lines of the scrolls $\Delta^{3}, \Phi^{3}$.

So by the transformation ( $P, Q$ ) the chord $l$ passes into the system consisting of $l$ itself, the tangents $s_{1}, s_{2}$ and a twisted cubic.

Evidently a trisecant $t$ is transformed into that line to be counted thrice and the langents in the three points it has in common with $\sigma^{4}$.
If $l$ touches $\sigma^{4}$ in $S_{13}$, the scroll $\mathscr{P}^{8}$ becomes a cone with nodal edge $l$. In the osculating plane of $\sigma^{4}$ in $S_{12} q$ lies along $l$; so this plane is common tangential plane of $\boldsymbol{A}^{3}$ and $\boldsymbol{\Phi}^{3}$, having still in common the triserant through $S_{12}$. The residual intersection $\lambda^{3}$ touches in $S_{12}$ the tangent of $\sigma^{4}$.
§ 10. If $l$ is unisecant of $\sigma^{4}$ in $S$ the curve $\lambda^{0}$ breaks up into the tangent $s$ of $a^{4}$ in $S$ and a curve $\iota^{6}$. The polar line $l^{\prime}$ of $l$ becomes chord of $\iota^{5}, s$ being one of the three chords cutting $l$ and $l^{\prime}$. The plane $l^{\prime} S$ touches $H^{3}$ in $S$ and is therefore polar plane of $P \equiv S$; it contains the tangent $s$ and the trisecant of $\sigma^{4}$ on which $S$ lies. Of the three variable points $Q$ common to $l^{5}$ and a plane through $l^{\prime}$, two coincide with $S$ and only one lies outside $S$.

Any plane through $l$ contains besides $S$ three points $Q$ and has therefore in $S$ two points with $\lambda^{5}$ in common. Also the plane $l^{\prime} S$ not passing through $l$ has in $S$ two points in common with $\lambda^{\circ}$; so $S$ is a node of $\lambda^{5}$. The plane $l s$ contains beside $S$ only one point $Q$; so it passes through the nodal tangents of the node. So to a unisecant corresponds a twisted quintic with a node.

The curve is of rank eight, through $l$ passing four common tangential planes of $\sigma^{4}$ and $\iota^{5}$.
