Schuh, F., The locus of the pairs of common points of four pencils of surfaces, in: KNAW, Proceedings, 9 II, 1906-1907, Amsterdam, 1907, pp. 555-566

This PDF was made on 24 September 2010, from the 'Digital Library' of the Dutch History of Science Web Center (www.dwc.knaw.nl) > 'Digital Library > Proceedings of the Royal Netherlands Academy of Arts and Sciences (KNAW), http://www.digitallibrary.nl'
case, it is easy to reason that $P P^{\prime \prime}$ coincides with $A B, C D$ or $E F$ and so the locus proper consists of these three lines and there is no envelope proper. The part improper of the locus however consists of six conics $A B C D E, A B C D F, A B E F C, A B E F D, \quad C D E F A$ and $C D E F B$, the part improper of the envelope of the six points $A, B, C, D, E$ and $F$. The total locus is thus of order fifteen, the total envelope of class six, so that for arbitrary position of the pencils of conics this sane holds for the locus proper and the envelope proper.

Sncek; Nov. 1906.

Mathematics. - "The locus of the pair"s of common points of four pencils of surfaces." By Dr. F. Schor. (Communicated by Prof. P. H. Schouts).
(Communicated in the meeting of December 29, 1906).

1. Given four pencils of surfaces $\left(F_{r}\right),\left(F_{s}\right),\left(F_{t}\right)$ and $\left(F_{n}\right)$ respectively of order $r, s, t$ and $u$. The base-curves of those pencils can have common points or they can in part coincide, in consequence of which of three arbitrary surfaces of the pencils $\left(F_{s}\right),\left(F_{t}\right)$ and $\left(F_{u}\right)$ the number of points of intersection differing from the base-curves can become less than $\dot{s} t u$; we call this number $a$, calling it $b$ for the pencils $\left(F_{2}\right),\left(F_{t}\right)$ and $\left(F_{u}\right), c$ for the pencils ( $F_{v}$ ) $\left(\dot{F}_{s}\right)$ and $\left(F_{u}\right)$ and $d$ for the pencils $\left(F_{1}\right),\left(F_{s}\right)$ and $\left(F_{1}\right)$. We now put the question:

What is the order of the surface formed by the pairs of points $P$ and $P^{\prime}$, through which a surface of each of the four pencils is possible?

If the points $P$ and $P^{\prime}$ do not lie on the base-curves we call the locus formod by those points the locus proper $L$ on which of course still curves of points $P$ may lie for which the corresponding point $P^{\prime}$ lies on one of the base-curves. If one triplet of pencils furnishes at least several points of intersection which are situated for all surfaces of those pencils on one of the base-curves, then there is a surface that cloes satisfy the question but in such a manner that if we assume $P$ arbitrarily on this surface the point $P^{\prime}$ belonging to it is to be found on one of the base-curves; this surface we call the part improper of the locus, whilst both surfaces together are called the total locus.
2. To determine the order $n$ of the locus proper $L$ we find the points of intersection with an arbitrary right line $l$. On $l$ wo take
an arbitrary point $Q_{\text {vat }}$ and we bring through that point surfaces $F_{s}, F_{t}$ and $F_{u}$ of the pencils ( $F_{s}$ ), ( $F_{t}$ ) and ( $F_{u}$ ). Through each of the $a-1$ points of intersection of those surfaces not situated on the base-curves of those surfaces we bring a surface $F_{7}$. These $a-1$ surfaces $F_{3}$ intersect the right line $l$ together in $(a-1) r$ points $Q_{n}$, which we make to correspond to the point $Q_{s t u}$. The coincidences of this correspondence are: $1^{\text {st }}$ the points $Q_{\text {rstu }}$ determining four surfaces which intersect one another once more in a point not lying on the base-curves, thus the $n$ points of intersection with the surface $L, 2^{\text {nd }}$ the points of intersection with the surface $R_{\text {stu }}$ belonging to the pencils $\left(F_{s}\right),\left(F_{t}\right)$ and $\left(F_{u}\right)$, the locus of the points $S$ determining three surfaces whose tangential planes in $S$ pass through one line.

To find the number of coincidences we have to determine the number of points $Q_{\text {s }^{\prime} u}$ corresponding to an arbitrary point $Q$, of $l$. To this end we take on $l$ a point $Q_{\text {tu }}$ arbitrarily and bring through it an $F_{t}$ and an $F_{u}$. Through each of the $b$ points of intersection of these surfaces with the surface $F_{r}$ through $Q$, (not lying on the base-curves) we bring an $F_{s}$, which $b$ surfaces $F_{0}$ intersect together the line $l$ in $b s$ points $Q_{s}$ which we make to correspond to $Q_{|l|}$. To find the number of points $Q_{l u}$ corresponding to an arbitrary point $Q_{s}$ of $l$ we take $Q_{a}$ arbitrarily on $l$, we bring through $Q_{s}$ an $F_{\text {, }}$, and throngh $Q_{u}$ an $F_{u}$ and throngh each of the $c$ points of intersection of those surfaces with $F_{r}$ an $F_{t}$, which furnish $c$ surfaces $F_{l}$ cuting $l$ in ct points $Q_{l}$; reversely to $Q_{t}$ belong du points $Q_{u,}$, so that we find between the points $Q_{u}$ and $Q_{L}$ a (ct, du)-correspondence, of which the $c t+d u$ coincidences give the points $Q_{1 \prime}$ belonging to the point $Q_{s}$. So between the points $Q_{l u}$ and $Q_{s}$ cexists a $(b s, c t+d u)$-correspondence, of which the coincidences consist of the $r$ points of intersection of $l$ with the surface $l$, through $Q_{r}$ and of the points $Q_{s t u}$ corresponding to $Q_{r}$; the number of these thus amounts to $b s+c t+d u-r$.

So between the points $Q_{s t u}$ and $Q_{\text {. }}$. there is an ( $n$ - $r, b s+c t+(l u-r)$ correspondence with $a r+b s+c t+c l u-2 r$ coincidences. To find oul of this the number of points $Q_{\text {sth }}$ we must first determine the order of the surface $R_{\text {sta }}$.

This surface may be regarded as the surface of contact of the surfaces of the pencil ( $F_{s}$ ) with the movable curves of intersections $C_{\text {al }}$ of the surfaces of the pencils $\left(F_{t}\right)$ and $\left.\left(F_{u}\right)^{1}\right)$. So the question is:

[^0]3. To determine the order of the surface of contact of a twofold infinite system of twisted curves and a singly infinite system of surfaces.

To this end we shall first suppose the two systems to be arbitrary.
To determine the order of the surface of contact we count its points of intersection with an arbitrary right line $l$. To this end we consider the envelope $E_{1}$ of the $\propto^{2}$ tangential planes of the curves of the system in their points of intersection with $l$ and the envelope $E_{3}$ of the $\infty^{1}$ tangential planes of the surfaces of the system in their points of intersection with $l$.
The common tangential planes not passing through $l$ of both envelopes indicate by means of their points of intersection with $l$ the points of intersection of $l$ with the surface of contact.

In order to find the class of the envelope $E_{1}$ (formed by the tangential planes of a regulus with $l$ as directrix) we determine the class of the cone enveloped by the tangential planes passing through an arbitrary point $Q$ of $l$. If the system of curves is such that $\varphi$ curves pass through an arbitrary point and $\psi$ curves touch a given plane in a point of a given right line, the tangential planes of $E_{1}$ through $Q$ envelope the $\mathscr{\rho}$ tangents in $Q$ of the curves of the system through $Q$, and the line $l$ counting $\psi$ times; for each plane through $l$ is to be regarded $\psi$ times as tangential plane, there being $\psi$ curves of the system cutting $l$ and having a tangent situated in this plane. The envelope $E_{1}$ is thus of class $\varphi+\psi$ and has $l$ as $\psi$-fold line ${ }^{1}$ ).

To find the class of the envelope $E_{1}$ we determine the number of its tangential planes through an arbitrary point $Q$ of $l$. If now the system has $\mu$ surfaces through a given point and $\boldsymbol{v}$ surfaces touching a given right line, the tangential planes of the envelope passing throngh $Q$ are the tangential planes in $Q$ to the $\mu$ surfaces passing through $Q$ and the tangential planes of the $v$ surfaces touching $l$. So the envelope $E_{2}$ is of class $\mu+v$ with $v$ tangential plunes through $l$.

Hence both envelopes hare $(\varphi+\psi)(\mu+v)$ common tangential planes. Each of the $v$ tangential planes of $E_{3}$ passing through $l$ is however: a $\psi$-fold tangential plane of $E$, and so it counts for $\psi$ common tangential planes. So for the number of common tangential planes not passing through $l$, thus the number of points of intersection of $l$ with the surface of contact we find:

$$
(\varphi+\psi)(\mu+v)-\psi v=\varphi v+\psi \mu+\varphi \mu,
$$

therefore:

[^1]The surface of contact of a system ( $(\mathcal{p}, \psi)$ of $\infty^{2}$ twisted curves ${ }^{1}$ ) and a.system ( $\mu, \nu)$ of $\infty^{1}$ surfaces $^{2}$ ) is of order $\left.\varphi \nu+\psi \mu+\varphi \mu^{3}\right)$.
4. To determine the order of the surface of contact ${ }^{1}$ ) of the systems $\mu_{1}, v_{1}$ ) , $\left(\mu_{2}, v_{2}\right)$ and ( $\mu_{3}, v_{3}$ ) each of $\infty^{1}$ surfaces, we regard the system ( $\boldsymbol{\varphi}, \psi)$ of the curves of intersection of the systems $\left(\mu_{1}, \nu_{1}\right)$ and $\left(\mu_{2}, r_{2}\right)$. Of these curves of intersection $\mu_{1} \mu_{2}$ pass through a given point, so $\varphi=\mu_{1} \mu_{2}$. The $\psi$ points, where the curves of intersection touch a given plane in a point of a given right line, are the points of intersection of that given line with the curve of contact of the systems $\left.\left(\mu_{1}, v_{1}\right)^{5}\right)$ and $\left(\mu_{2}, v_{2}\right)$ of plane curves, according to which the giren plane intersects the systems of surfaces $\left(\mu_{1}, v_{1}\right)$ and $\left(\mu_{2}{ }^{-} v_{2}\right)$. This curve of contact is of order $\mu_{1} v_{2}+\mu_{2} v_{1}+\mu_{1} \mu_{2}$, thus:

$$
\psi=\mu_{1} v_{2}+\mu_{2} v_{1}+\mu_{1} \mu_{2} .
$$

The surface of contact to be found is thus the surface of contact of a system ( $\mu_{1} \mu_{2}, \mu_{1} v_{2}+\mu_{2} v_{1}+\mu_{1} \mu_{2}$ ) of $\infty^{2}$ twisted curves and a system ( $\mu_{3}, \nu_{3}$ ) of $\infty^{1}$ surfaces, so that we find:

The surface of contact of three systems $\left(\mu_{1}, v_{1}\right),\left(\mu_{2}, v_{2}\right)$ and $\left(\mu_{3}, v_{3}\right)$ of $\infty^{1}$ surifaces is of order

$$
\mu_{2} \mu_{3} \nu_{1}+\mu_{3} \mu_{1} \nu_{2}+\mu_{1} \mu_{2} v_{3}+2 \mu_{1} \mu_{2} \mu_{3} .
$$

If the three systems are the pencils $\left(F_{s}^{\prime}\right),\left(F_{t}\right)$ and $\left(F_{u}\right)$ we have

$$
\begin{aligned}
& \mu_{1}=\mu_{2}=\mu_{3}=1, \\
& v_{1}=2(s-1) \quad, \quad v_{3}=2(t-1) \quad, \quad v_{3}=2(u-1) .
\end{aligned}
$$

So we find:
Thu surface of contact $F_{\text {stu }}$ of the three pencils of surfaces ( $F_{s}$ ), $\left(F_{t}\right)$ and $\left(F_{u}\right)$ is of order

[^2]$$
2(s+t+u-2)
$$
5. To return to the question which gave rise to the preceding considerations we find for the number of points $Q_{\text {nstu }}$ on the arbitrary line $l$, which are the points of intersection of $l$ with the locus proper $L$ :
\[

$$
\begin{aligned}
& a r+b s+c t+d u-2 r-2(s+t+u-2)= \\
= & a r+b s+c t+d u-2(r+s+t+u)+4
\end{aligned}
$$
\]

So we find:
The locus $L$ of the pairs consisting of two movable points common to a surface out of each of the pencils $\left(F_{1}\right),\left(F_{s}\right),\left(F_{t}\right)$ and $\left(F_{u}\right)$ of orders $r, s, t$ and $u$, and not lying on the base-curves, is a surface of order.

$$
a r+b s+c t+d u-2(r+s+t+u)+4
$$

Here $a$ is the number of points of intersection not necessarily situated on the base-curves of the pencils $\left(F_{s}\right),\left(F_{1}\right)$ and $\left(F_{u}\right) ; b$ the analogous number for the pencils $\left(F_{1}\right),\left(F_{t}\right)$ and $\left(F_{u}\right)$, etc.
6. It the penculs have an arbitrary situation with respect to each other, then $a=s t u$, etc., so that then the order of the locus becomes

$$
4(r s t u+1)-2(r+s+t+u)
$$

That order is lowered when three of the base-curves have a common point or two of the base-curves have a common part, which lowering of the order can be explained by separation as Inng as the total locus is definite, i. e. as long as the four base-curves have no common point and no triplet of base-curves have a common part. For, if $A_{\text {stu }}$ is a common point of four base-curves then the surfaces of the four pencils passing through an enturely arbitrary point $P$ have another second point in common, namely $A_{\text {stu }}$; if $B_{s t u}$ is a curve forming part of the base-curves $B_{s}, B_{l}$ and $B_{l}$ of the pencils $\left(F_{s}\right),\left(F_{l}\right)$ and $\left(F_{u}\right)$, then the surfaces of the penculs passing through an arbitrary point $P$ have moreover the points of intersection in common of $\mathcal{B}_{\text {stu }}$ with the surface $F_{\text {, through }} P$; so in both cases the arbitrary point $P$ belongs 10 the total locus.

If the basecurves $B_{s}, B_{t}$ and $B_{u}$ have a common point $A_{\text {stu }}$ then on account of that point the number $a$ is diminished by unity without having any influence on $b, c$ and $d$. The order of $L$ is thus lowered by $r$ on account of it, which is immediately explained by the fact that the surface $F_{\text {, passing }}$ through $A_{\text {sta }}$ separates itself from the locus.

If the base-curves $B_{t}$ and $B_{u}$ have a curve $B_{t u}$ in common of ${ }^{-}$ which for convenience we suppose that 'it does not intersect the base-curves $B_{1}$ and $B_{s}$, this $B_{t t}$ has no influence on $c$ and $d$, whilst $a$ is lowered with $s m$ and $b$ with $r m$, where $m$ represents the order of the curve $B_{l u}$; for, when $F_{s}, F_{t}$ and $F_{u}$ are three arbitrary surfaces always $s m$ points of intersection lie on $B_{u l}$. The order of $L$ is thus lowered with $2 r s m$ by $B_{l u}$. This can be explained by the fact, that the locus of the curves of intersection $C_{\text {s }}$ of surffaces $F_{r}$ and $F_{s}$ passing throught a selfssome point of $B_{\text {tu }}{ }^{1}$ ) separates itself from the locus of $P$ and $P^{\prime}$. That the locus of those curves of intersection is really of order $2 r s m$ is easily evident from the points of intersection with an arbitrary line $l$. We can bring through an arbitrary point $Q$, of $l$ an $F$, cutting $B_{t u}$ in $r m$ points, through each of those points of intersection we bring an $F_{s}$, which rm surfaces $F_{s}$ cat the right line $l$ in rsm points $Q_{s}$. To $Q_{\text {, correspond }}$ $r s m$ points $Q_{s}$ and reversely. The $2 r s m$ concidences are the points' of intersection of $l$ with the locus of the curves of intersection $C_{/ s}$.
7. The base-curves $B_{r}, B_{s}, B_{l}$ and $B_{u}$ of the pencils are morefold curves of the surface $L$. If $A$, is a point of $B_{1}$ but not of the other base-curves, then $A_{2}$ is an ( $a-1$ )-fold point of $L$. For, the surfaces $F_{s}, F_{l}$ and $F_{u}$ through $A_{r}$ intersect one another in $a-1$ points, not lying on the base-curves, each of which points furnishes together with $A$, a pair of points satisfying the question. Each point of $B_{1}$ is thus an $(a-1)$-fold point, i.o. w. $B_{r}$ is $(a-1)$-fold curve of the surface $L$.

Let $A_{r s}$ be a point of intersection of the base-curves $B$, and $D_{s}$, but not a point of $B_{i}$ and $B_{u}$. An arbitrary point $P$ of the curve of intersection $C_{l u}$ of the surfaces $F_{t}$ and $-F_{u}$ throngh $A_{1 s}$ furnishes now together with $A_{l s}$ a pair of points $P P^{\prime}$ satisfying the question properly, as $A_{r s}$ is for each triplet of pencils a movable point of intersection not lying on the base-curves. If we let $P$ describe the curve $C_{l u}$, then the tangent $l_{r s}$ in $A_{2 s}$ to the curve of intersection of the surfaces $F_{r}$ and $F_{s}$ through $P$ describes the cone of contact of $L$ in the conic point $A_{s s}$. The tangents $m_{r}$ and $m_{s}$ in $A_{1 s}$ to $B$, and $B_{s}$ are ( $a-1$ ) resp. ( $b-1$ )-fold edges of the cone. This cone is cut by the plane through $m_{2}$ and $m_{s}$ only according to the line $m_{r}$ counting ( $a-1$ )-times and the line $m_{s}$ counting ( $b-1$ )-times, as another line $l_{\text {rs }}$ lying in this plane would determine two surfaces

[^3]$F_{1}$ and $F_{s}$ touching each other in $A_{25}$, whose curve of intersection, However, does not cut the curve $C_{t u}$. The tanyential cone of $L$ in $A_{1 s}$ is thus of order $a+b-2^{1}$ ).

Let $A_{1 s}^{(1)}$ be a point of a common part $B_{1 s}$ of the base-curves $B_{r}$ and $B_{s}$ but not a point of $B_{i}$ and $B_{u}$. We get a pair of points $P P^{\prime}$ with a point $P^{\prime}$ coinciding with $A_{i s}^{(1)}$ when the surfaces $F_{r}$ and $\dot{F}_{s}$ have in $A_{i s}^{(1)}$ a common tangential plane $V_{i s}$ and pass through a selfsame point $P$ of the curve of intersection $C_{t u}$ of the surfaces $F_{t}$ and $F_{u}$ through $A_{i s}^{(1)}$. If we let $P$ describe the curve $C_{u u}$, then on account of that between the planes $V_{r}$ and $V_{s}$, touching in $A_{r s}^{(1)}$ the surfaces $F_{r}$ and $F_{s}$ through $P$, a correspondence is arranged, where to $V_{r}$ correspond $b-1$ planes $V_{s}$ and to $V_{\mathrm{s}}$ correspond $a-1$ planes $V$, . One of the $a+b-2$ planes of coincidences is the plane through the tangents in $A_{1 s}^{(1)}$ to $B_{1 s}$ and $C_{t u}$; this plane furnishes no plane $V_{1 s}$. The remaining $a+b-\mathbf{3}$ planes of coincidence are planes $V_{r s}$ and indicate the tangential planes in $A_{r s}^{(1)}$ to the surface $L$. So $B_{r s}$ is an $(a+b-3)$-fold curve of $L$.
8. Let us then consider a common point $A_{r s t}$ of the base-curves $B_{r}, B_{s}$ and $B_{t}$. We get a pair of points $P P^{\prime}$ with a point $P^{\prime}$ coinciding with $A_{1 s t}$, when the tangential planes in $A_{1 s t}$ to $F_{1,} F_{s}$ and $F_{t}$ pass through one line $l_{1 s t}$ and these surfaces intersect one another again in a point $P$ of the surface $F_{u}$ @assing through $A_{2 s t}$. There are $\infty^{1}$ such lines $l_{1, t}$, forming the tangential cone of $\mathbb{L}$ in point $A_{1 s t}$. The tangents $m_{1}, m_{s}$ and $m_{t}$ in $A_{1 s t}$ to $\mathcal{B}_{1}, B_{s}$ and $B_{t}$ are $(a-1)$-, $(b-1)$ - and $(c-1)$-fold edges of that cone. So the plane through $m_{r}$ and $m_{s}$ furnisbes $a+b-2$ lines of intersection with the cone coinciding with $m_{r}$ and $m_{s}$. Moreover $c-2$ other lines $l_{r s t}$ lie in this plane. For, the surfaces $F_{r}$ and $F_{s}$ touching this plane intersect $F_{u}$ in $c-2$ points not lying on the base-curves; the surfaces $F_{t}$ through those points intersect the plane through $m_{r}$ and $m_{s}$ according to curves whose tangents in $A_{r s t}$ are the mentioned

[^4]Proceedings Royal Acad. Amsterdam. Vol. IX.
lines $l_{\text {rst }}$. So the tangentral cone of $L$ in $A_{\text {rst }}$ is of order $a+b+c-4^{1}$ ).
A point of intersection $A_{r s t}^{(1)}$ of $B_{r}$ with a common part $B_{s t}$ of the base-curves $B_{s}$ and $B_{t}$ is a conic point of $L$, the tangential cone of which is formed as in the previous case by $\infty^{1}$ lines $l_{r s t}$. The tangents $m_{r}$ and $m_{s t}$ in $A_{r s t}^{(1)}$ to $B_{r}$ and $B_{s t}$ are $(a-1)$ and $(b+c-3)$-fold edges of that cone. As no other lines $l_{\text {st }}$ lie in the plane through $m_{r}$ and $m_{s t}$, it is evident that the tangential cone of $L$ in $A_{r s t}^{(1)}$ is likiewise of order $a+b+c-4^{1}$ ).

Let $A_{r s t}^{(2)}$ be a point of a common part $B_{r s t}$ of the base-curves $B_{r}$, $B_{s}$ and $B_{l}$. The point $P^{\prime}$ of the pair of points $P P^{\prime}$ coincides with $A_{r s t}^{(2)}$ when the surfaces $F_{r}, F_{s}$ and $F_{t}$ have in $\Lambda_{r s t}^{(2)}$ the same tangential plane $\Gamma_{r s t}$ and cut one another in another point $P$ of the surface $F_{u}$ through $A_{r s t}^{(2)}$. If we now consider an $F_{r}$ and an $F_{s}$ having in $A_{r s t}^{(2)}$ the same tangential plane $V_{r s}$ and if we consider through each of the $c-1$ points of intersection of $F_{r}, F_{s}$ and $F_{u}$ not lying on the base-curves an $F_{t}$ of which we indicate the tangential plane in $A_{r s t}^{(2)}$ by $V_{t}$ then to $V_{r s}$ correspond $c-1$ planes $V_{t}$ and to $V_{t}$ correspond $a+b-1$ planes $V_{1 s}$ (as for given $V_{t} a(b, a)$-correspondence exists between $V_{r}$ and $V_{s}$ of which $V_{t}$ is one of the planes of coincidence). Among the $a+b+c-2$ planes of coincidence $V_{r s} V_{t}$ there are however three which give no plane $V_{r s t}$, namely the planes $V_{1 s}$, for which the corresponding surfaces $F_{r}$ and $F_{s}$ furnish with $F_{u}$ three points of intersection coinciding with $A_{r s}^{(2)}$. For this is necessary that $F_{u}$ touches in $A_{r s t}^{(2)}$ the movable intersection of $F_{r}$ and $F_{s}$. Now the tangents of those intersections for all surfaces $F_{r}$ and $F_{s}$ touching each other in $A_{1 s t}^{(2)}$ form a cubic cone having for double edge the tangent $m_{r s t}$ to $\mathcal{B}_{r s t}$ in point $\left.A_{i s t}^{(2)}{ }^{2}\right)$. This cone is cut by the tangential plane in $A_{r s t}^{(2)}$ to $F_{u}$ according to three lines, furnishing with $m_{r s t}$ planes $V_{r s}$ which are planes of coincidence
${ }^{\text {}}$ ) This order can also be determined out of the number of lines $l_{\text {rst }}$ in a plane E passing through $A_{1 s t}$. In this plane we find a ( $c-1, a+b-2$ )-correspondence between lines $l_{\text {Is }}$ and .lines $l_{l}$ of which however the line of intersection of $:$ with the tangential plane in $A_{r s t}$ to $F_{u}$ is a line of coincidence, but no line $l_{s t}$.
2) This is immediately evident if we take for $\left(F_{r}\right)$ a pencil of planes and for $\left(F_{s}\right)$ a pencil of quadratic surfaces all passing through the axis $B_{r}$ of the pencil of planes. The cone under consideration then becomes the cone of the generatrices of the quadratic surfaces passing through a given point of $B_{r}$. We can easily convince ourselves that the same result holds for arbitrary pencils of surfaces.
of $V_{r s}$ and $V_{1}$, but not planes $V_{r s t}$. So there are $a+b+c-5$ planes $V_{\text {st }}$, which are the tangential planes of $L$ in the point $A_{i s t}^{(9)}$, i. o. w. $B_{1 s t}$ is $(a+b+c-5)$-fold curve of surface $L$.
9. We then consider a common point $A_{\text {rstu }}$ of the four base-curves. We get a pair of points $P P^{\prime}$ with point $P^{\prime}$ coinciding with $A_{1}$ stu when $F_{1}, F_{s,}, F_{t}$ and $F_{u}$ have in $A_{v s t u}$ a common langent $l_{r s t u}$ and all pass once again through a selfsame point $P$. The $\infty^{1}$ lines $l_{\text {rstu }}$ form the tangential cone of $L$ in $A_{\text {rstu }}$. To determine the number of lines $l_{\text {rstu }}$ in an arbitrary plane $\varepsilon$ through $A_{r \text { siu }}$ we take in this plane an arbitrary line $l_{\text {rst }}$ through $\Lambda_{\text {rslu }}$ and we bring through the $d-1$ points of intersection (not lying on the base-curves) of the surfaces $F_{r}, F_{s}$ and $F_{t}$ touching $l_{r s t}$ the surfaces $F_{u}$, whose tangential planes in $\left\langle l_{\text {rstu }}\right.$ cut the plane $\varepsilon$ according to lives, which we shall call $l_{u}$. To $l_{\text {rst }}$ now correspond $d-1$ lines $l_{u}$ and to $l_{u}$ correspond $a+b+c-2$ lines $l_{r s t}$, as there exists between $l_{r s}$ and $l_{t}$ when $l_{u}$ is given a $(c, a+b)$-correspondence, of which $l_{u}$ and the line of intersection of $\varepsilon$ with the plane through the tangents in $\Lambda_{2 \text { ctu }}$ to $B_{r}$ and $B_{s}$ are lines of coincidence, but not lines $l_{s t}$. So there are $a+b+c+d-3$ lines of coincidence $l_{r s t} l_{u}$ of which however three are not lines $l_{r s t u}$. The common tangents in $A_{r s t u}$ of the surfaces $F_{r}$, $F_{s}$ and $F_{t}$ possessing three points of intersection coinciding with $A_{r \text { stu }}$ and where therefore the intersection of two of those surfaces shows a contact of order two to the third, form namely a cubic cone ${ }^{1}$ ) of which the lines of intersection with $\varepsilon$ are lines of coincidence but not lines $l_{\text {rstu }}$. So in $\varepsilon$ lie $a+b+c+d-6$ lines $l_{\text {rstu }}$, i. o. w. the tangential cone of $L$ in $A_{\text {sttu }}$ is of order $a+b+c+d-6^{2}$ ).

[^5]The preceding considerations hold invariably for a point $A_{r v u}^{(1, u}$ lying on the base-curves $B_{r}$ and $B_{s}$ and the common part $B_{l u}$ of the base-curves $B_{t}$ and $B_{u}{ }^{1}$ ).
In a point of intersection $A_{r s t u}^{(2)}$ of $B_{r s}$ and $B_{t u}$ the tangential cone is likewise of order $a+b+c+d-6$ as that cone has the tangents $m_{r s}$ and $m_{t u}$ to $B_{1 s}$ and $B_{t u}$ as $(a+b-3)$ and $(c+d-3)$ fold edges, whilst in the plane through $m_{2 s}$ and $m_{\text {lu }}$ no other right lines $l_{\text {ssiu }}$ are lying.
A point of intersection $A_{r o t u}^{(3)}$ of $B_{r}$ and $B_{s t u}$ is also $a(a+b+c+c-6)$ fold point of $L$ as $m_{1}$ and $m_{\text {stu }}$ are $(a-1)$ - and $(b+c+d-5)$ fold edges of the tangential cone and the only lines of intersertion of that cone with the plane through $m_{1}$ and $m_{\text {stu }}$.
If finally $A_{\text {rstu }}^{(4)}$ is a point of a common part $B_{r s t u}$ of the four basecurves, then the point $P^{\prime}$ of the pair of points $P P^{\prime \prime}$ coincides with $A_{i s t u}^{(4)}$ when the surfaces $F_{n}, F_{s}, F_{t}$ and $F_{u}$ have in $\Lambda_{r s t u}^{(4)}$ the same tangential plane $V_{\text {stu }}$ and all pass through a same point $P$. Let us now assume an arbitrary plane $V_{\text {st }}$ passing through the tangent $m_{r s t u}$ in $A_{1 s l u}^{(4)}$ to $B_{1 s t u}$. The surfaces $F_{i}, F_{s}$ and $F_{t}$ touching this plane in $A_{r s t u}^{(4)}$ cut one another in $d-1$ points $P$, through which we bring surfaces $F_{u}$, of which we call the tangential planes in $A_{r s t u}^{(4)} V_{u}$. Thus we obtain a correspondence, where to $V_{r s t}$ correspond $d-1$ planes $V_{u}$ and reversely to $V_{u}$ correspond $a+b+c-1$ planes $V_{1 s t} ;$ for when $V_{u}$ is given there is between $V_{1 s}$ and $V_{t}$ a $(c, a+b)$ correspondence, of which $V_{u}$ is plane of coincidence, but not a plane $V_{1 s t}$. So there are $a+b+c+d-2$ planes of coincidence $V_{1 s t} V_{u}$, of which however five are not planes $V_{1 \text { stu }}$. These are namely the tangential planes of the surfaces $F_{r}, F_{s}$ and $F_{t}$ of which one more point of intersection coincides with $A_{\text {sstu }}^{(4)}$ which

[^6]occurs five times ${ }^{1}$ ). So there remain $a+b+c+d-7$ planes $V_{\text {sta }}$ which are the tangential planes of $L$ in the point $A_{\text {stu }}^{(4)}$, so that $B_{\text {rstu }}$ is a $(a+b+c+d-7)$ fold curve of $L$.
10. So we find:

Of the locus proper $L$ of the pairs of points $P$ and $P^{\prime}$ the base-curve $B$, of the pencil ( $F_{r}$ ) is (a-1)-fold curve, the common part $B_{1 s}$ of the base-curves $B_{1}$ and $B_{s}$ is $(a+b-3)$-fold curve, the common part $B_{1 \text { st }}$ of the base-curves $B_{r}, B_{s}$ and $B_{t}$ is $(a+b+c-5)$ fold curve and the common part $B_{1 s t}$ of the four base-curves is $(a+b+c+d-7)$-fold curve. The points of intersection of the base-curves are conic points of $L$, namely a point of intersection of $B_{r}$ and $B_{s}$ is $(a+b-2)$-fold point, a point of intersection of $B_{r}, B_{s}$ and $B_{t}$ or of $B_{1}$ and $B_{s t}$ is $(a+b+c-t)$-fold point and a point of intersection of $B_{r}, B_{s}, B_{t}$ and $B_{u}$ or of $B_{r}, B_{s}$ and $B_{t u}$ or of $B_{2 s}$ and $B_{t u}$ or of $B_{1}$ and $B_{s t u}$ is $(a+b+c+d-6)$ fold point. ${ }^{\text {a }}$ )
11. The base-curves of the pencils are not the only singular curves of the surface $L$. There are namely $\infty^{1}$ triplets of points lying on a surface of each of the pencils. These triplets of points form a double curve of $L$. If $P, P^{\prime}, P^{\prime \prime}$ is such a triplet and if $P 1$ and $P 2$ are the sheets through $P$ of the surface, then the sheets $P^{\prime} 1$ and $P^{\prime \prime} 2$ correspond to them. Through $P^{\prime}$ passes another sheet $P^{\prime} 3$ and through $P^{\prime \prime}$ a sheet $P^{\prime \prime} 3$ which sheets correspond mutually. The pair of points not lying on the base-curves is movable along the sheets $P 1, P^{\prime} 1$, along the sheets $P 2, P^{\prime \prime} 2$ and along the sheets $P^{\prime} 3, P^{\prime \prime} 3$, on the basc-curve a third point then joins the pair.

Further there is still a finte number of quadruples of points,

[^7]intersections of surfices $F_{s}$ and $F_{t}$ touching each other in $A_{1 s t u}^{(1)}$ form a cubsc cone having the tangent $m m_{s t u}$ to $B_{r \text { rt }}$ as double line. Such an intersection shows to the surface $F$, a contact of order two when it touches the movable intersection of $F_{r}$ and $F_{l}$, so if its tangent in $A_{i s t u}^{(t)}$ lies on the cubic cone belonging to the pencils ( $F_{1}$ ) and ( $F_{l}$ ). As this last cone has also $m_{\text {rsta }}$ as double edge, both cones have $9-4=5$ lines of intersection differing from $m_{1 s i n}$ whech connected with $m_{1 \text { stu }}$ furnish the five planes under consideration.
${ }^{2}$ ) If the total locus is not indefinite, i. o. w. if there is no point common to the four base-curves then $B_{1}$ is a (stu - 1) fold curve and $B_{r s}$ a (stut +rtut - 2) fold curve of the total locus whilst a point of intersection of $B_{r}$ and $B_{s}$ is a (stu $+r t u-2$ )-fold point and a point of intersection of $B_{1}, B_{s}$ and $B_{t}$ or of $B_{r}$ and $B_{a l}$ a $(s t u+r t u+r s u-3)$ fold point of it.
through which passes a surface out of each of the pencils. Through the points $P, P^{\prime \prime}, P^{\prime \prime}$ and $P^{\prime \prime \prime}$ of such a quadruple pass three sheets of the surface $L$ and three branches of the double curve. The 12 branches of the double curve through those four points we can call $P_{1}, P^{2}, P^{\prime}, P^{\prime} 1, P^{\prime} 2, P^{\prime} 4, P^{\prime \prime} 1, P^{\prime \prime} 3, P^{\prime \prime} 4, P^{\prime \prime \prime} 2, P^{\prime \prime \prime} 3, P^{\prime \prime \prime} 4$, in such a way that the triplet of points is movable along the branches $P 1, P^{\prime} 1, P^{\prime \prime} 1$, along $P 2, P^{\prime} 2, P^{\prime \prime \prime} 2$, along $P 3, P^{\prime \prime} 3, P^{\prime \prime \prime} 3$ and along $P^{\prime} 4, P^{\prime \prime} 4, P^{\prime \prime \prime} 4$. If the sheet of $L$ passing through $P 1$ and $P 2$ is called $P 12$, then the corresponding sheets (i. e. sheets along which the pair of points not lying on the double curve is movable) are $P 12$ and $P^{\prime} 12, P 13$ and $P^{\prime \prime} 13$, etc.

- Geophysics. - "Current-meusurements at various depths in the

North Sea." (First communication). By Prof. C. H. Wind, Let. A. F. H. Dalbuisen and Dr. W. E. Ringer.

In the year 1904 accurate measurements of the currents in the North Sea ${ }^{1}$ ) were started by the naval leutenant A. M. van RoosendaAL, at the time detached to the "Rijksinstituut voor het Onderzoek der Zee", having been proposed and guided by the Dutch delegates to the International Council for the Study of the Sea.

By him four apparatus were put to the test, viz. 2 specimens of the current-meter of Pettersson ${ }^{2}$ ), one of that of Nansen ${ }^{3}$ ) and one of that of Erman ${ }^{4}$ ), all destined to determine the direction and the velocity of the current at every depth.

The experiments were partly made on the light-ship "Haaks", where `Dr. J. P. yan der Stok, the Marine Superintendent of the Kon. Nederl. Meteorologisch Instituut, also took part in them. Other experiments were made in the harbour of Nieuwediep and further, from the research-steamer "Wodan", in the open North Sea at a station (H2) of the Dutch seasonal cruises ${ }^{5}$ ), situated at Lat. $53^{\circ} 44^{\prime} \mathrm{N}$. and Long. $4^{\circ} 28^{\prime} \mathrm{E}$.

[^8]
[^0]:    り) We shall call this surface the surface of contact of the three pencils meaning by this that in a point of this "surface of contact" the surfaces of the pencils, thongh not touching one another, admit of a common langent.

[^1]:    ${ }^{1}$ ) The regulus as locus of points has however line $l$ as $\varphi$-fold line.

[^2]:    ${ }^{1}$ ) System with $\varphi$ curves through a given point and $\psi$ curves cutting a given line and touchng in the point of intersection a given plane through that linc.
    ${ }^{2}$ ) System with $\mu$ surfaces through a given point and $\nu$ surfaces touching a given right line.
    ${ }^{3}$ ) This result is also mmediately deducble from the Schubert formula

    $$
    x p^{2}=p^{\prime 3} \cdot G+p^{\prime} g_{e}^{\prime} \cdot p^{9} g_{e}+p^{\prime 3} \cdot p^{2} g_{e}
    $$

    (Kalkul der abzahlenden Geometrie, formula 13, page 292) for the number of common elements with a point lying on a given line of a system $\Sigma^{\prime}$ of $\infty^{3}$ and a system $\Sigma$ of $\cos ^{1}$ right lines with a point on it. If we take for $\Sigma^{\prime}$ the tangents with point of contact of the system of curves $(p, \psi)$ and for $\Sigma$ the tangents with point of contact of the system of surfaces $(\mu, \nu)$, then

    $$
    p^{\prime s}=\varphi, p^{\prime} g_{\epsilon}^{\prime}=\downarrow, G=v, p^{2} g_{e}=\mu,
    $$

    whilst $x p^{2}$ is the order of the surface of contact.
    ${ }^{4}$ ) Locus of the points, where the surfaces of the thrce systems have a common tangent.
    ${ }^{\text {j }}$ ) System of $\infty^{1}$ curves of which $\mu_{1}$ pass through a given pont and $\nu_{1}$ touch a given tight line.

[^3]:    ${ }^{1}$ ) If $B_{t u}$ cuts the curve $B_{s}$ in a point $A_{s t u}$, then the surface $F_{r}$ passing through Artu separates itself from the locus of the cuives of intersection Crs.

[^4]:    ${ }^{1}$ ) The order of this cone can also be found out of the number of lines of intersection with an arbitrary plane $\varepsilon$ through $A_{r s}$. If $l_{r}$ and $l_{s}$ are the lines of intersection of $\varepsilon$ with the tangential planes in $A_{r s}$ to the surfaces $F_{r}$ and $F_{s}$ through $P$, then to $l_{r}$ correspond $b-1$ lines $l_{s}$ and to $l_{s}$ correspond $a-1$ lines $l_{r}$, so that in the plane. lie $a+b-2$ lincs $l_{r s}$.

[^5]:    ${ }^{1}$ ) This is again evident when taking for ( $F_{1}$ ) and ( $F_{0}$ ) pencils of planes with coplanar axes $B_{r}$ and $B_{s}$ and for ( $F_{t}$ ) a pencil of quadratic surfaces passing through a line containing the point of intersection $S$ of $B_{r}$ and $B_{r}$. The line of intersection of the planes $F_{1}$ and $F_{s}$ shows only then a contact of order two to $F_{t}$ when that line of intersection lies entirely on $F$, so that the cone under consideration becomes again the cone of the generatrices of the quadratic surfaces passing through $S$.
    ${ }^{2}$ ) That order can also be found out of the lines of intersection with the plane $V_{r s}$ through the tangents $m_{r}$ and $m$ in $A_{s i t}$ to $B_{r}$ and $B_{s}$. Those lines of intersection are: the line $m_{r}$, counting ( $a-1$ )-times, the line $m_{\mathrm{s}}$ counting ( $b-1$ )times and $c+d-4$ other lines. This last amount we find by drawing in plane $V_{r s}$ an arbitrary line $l_{l}$ through $A_{r s i u}$. The surface $F_{l}$ touching $l_{l}$ cuts the surfaces $F_{r}$ and $F_{s}$ touching $V_{r s}$ in $d-1$ points (not lying on the base-curves) through which points we bring surfaces $F_{u}$ whose tangential planes in $A_{r s k}$ cut the plane $V_{r s}$ according to lines to be called $l_{u}$. Between the lines $l_{t}$ and $l_{u}$ we now have a $(d-1, c-1)$-correspondence of which the nodal tangents in $A_{\text {retu }}$ of the intersection of the surfaces $F_{r}$ and $F_{s}$ touching $V_{r s}$ are lines of coincidence. The remaining $c+d-4$ lines of coincidence are lines $l_{\text {rstu }}$.

[^6]:    1) It is also casy to see from the lines of intersection with the plane V.tu through the tangents $m_{s}$ and $m_{t u}$ to $B_{s}$ and $B_{t / n}$ that the tangential cone in $A_{r s h n}^{(1)}$ is of order $a+b+c+a-6$. The line $m_{s}$ counts for $b-1$ lines of intersection, the line $m_{t u}$ for $c+d-3$. Further, the surfaces $F_{s}, F_{l}$ and $F_{n}$ touching $\nabla_{\text {stu }}$ cut one another in $a-2$ points not lying on the base-curves; through those points we bring surfaces $F_{r}$, whose tangential planes in $A_{r s t u}^{(1)}$ cut the plane $V_{\mathrm{s} \text { tu }}$ along to lines which lie on the tangential cone.
[^7]:    1) The number five is found in the following way. The tangents of the movable
