Mathematios. - "The equivalence in $R_{n}$ of the n-dimensional simplex star and the spherical neighbourhood." By Wilfrid Wirson. (Communicated by Prof. L. E. J. Brouwer.)
(Communicated at the meeting of December 27, 1924).
The object of this paper is to prove the theorems I and II stated beneath. So far as the writer is aware these theorems have not yet been explicitly stated and proved, but have been implicitly used in several topological investigations. Some related theorems are stated and proved by H. Kneser in a paper in these Proceedings, the proof sheets of which I have seen through the intermediation of Prof. Brouwer. ${ }^{1}$ )

The Simplex star.
In the $m$-dimensional number space $R_{m}$ consider a finite number of $n$-dimensional simplexes, $(n \leqslant m)$ of common vertex $A_{0}$ and such that:
(a). Any ( $n-1$ )-dimensional face of vertex $A_{1}$ is common to two and only two $n$-dimensional simplexes;
(b). Any two $n$-dimensional simplexes have in common either (1) no point other than $A_{0}$, or (2) one $p$-dimensional face and all its ( $p-k$ )-dimensional faces, $(p \leqslant n-1 ; k=1,2, \ldots, p$ ).

The set of points constituting these simplexes and their boundaries is called an $n$-dimensional simplex star of centre $A_{0}$; those ( $n-p$ )dimensional faces, $(p=1,2, \ldots, n)$, of which $A_{0}$ is not a vertex are called the boundary of the star while the remaining points are called the interior.

Regular subdivision of a simplex star. ${ }^{2}$ )
Let $\alpha_{i}$ be the number of $i$-dimensional simplexes, $(i=0,1, \ldots, n)$, of the $n$-dimensional star $S_{n}$, so that any simplex of $S_{n}$ may be written $a_{j}^{i},\left(i=0,1, \ldots, n ; j=1,2, \ldots, a_{i}\right)$, the $a_{j}^{0},\left(j=1,2, \ldots, \alpha_{0}\right)$, being the vertices. In the interior of $a_{j}^{i}$ take an arbitrary point $P_{j}^{i}, P_{j}^{0}$ being the vertex $a_{j}^{0}$, and subdivide $S_{n}$ into a set $\bar{S}$ of $n$ dimensional simplexes, in the following way:

[^0](0) The vertices of $\bar{S}$ are the points $P_{j}^{i},\left(i=0,1, \ldots, n ; j=1,2, \ldots, a_{i}\right)$.
(1) The 1 -dimensional simplexes of $\bar{S}$ are the segments which join the point $P_{j}^{i}$ to each vertex of $\bar{S}$ in the boundary of $a_{j}^{i}$, ( $i=1,2, \ldots, n ; j=1,2, \ldots, \alpha i$ ).
(k) A $k$-dimensional simplex of $\bar{S}$ is the set of points on all segments joining a point $P_{j}^{i}$ to the points of a $(k-1)$-dimensional simplex of $\bar{S}$ in the boundary of $a_{j}^{i},\left(i=k, k+1, \ldots, n ; j=1,2, \ldots, a_{i}\right)$.
(n) An $n$-dimensional simplex of $\bar{S}$ is the set of points on all segments joining a point $P_{j}^{n}$ to the points of an ( $n-1$ )-dimensional simplex of $\bar{S}$ in the boundary of $a_{j}^{n},\left(j=1,2, \ldots, \alpha_{n}\right)$.

It follows from these definitions that any $n$-dimensional simplex of $\bar{S}$ has the form $P_{q}^{0} P_{r}^{1} \ldots P_{s}^{n}$ and that the number of simplexes in $\bar{S}$ is finite (being $(n+1)$ ! times the number in $S_{n}$ ).

Theorem 1. Any point $P$ of the interior of an $n$-dimensional star $S_{n}$ is the centre of an $n$-dimensional star $S_{n}^{\prime}$ composed of simplexes of a regular subdivision $\bar{S}$ of $S_{n}$.

Let $P$ be in the $k$-dimensional simplex $a_{s}^{k}$ of $S_{n},(0 \leqslant k \leqslant n)$. Choose the subdivision $\bar{S}$ so that $P_{s}^{k}=P$, and let

$$
P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{\eta}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{u-1} P_{v v}^{n}=\bar{a}_{v v}^{n}
$$

be any $u$-dimensional simplex of $\bar{S}$ of vertex $P_{s}^{k}$.
From the definitions (0), (1), $\ldots,(n)$ it follows that
$P_{l}^{0} P_{n}^{1} P_{n}^{2} \ldots P_{r}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{n}^{n-1} P_{v}^{n}$ is in the simplex $a_{v 0}^{n}$ of $S_{n}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{n-1}$ is in the ( $n-1$ )-dimensional face $a_{v}^{n-1}$ of $a_{w}^{n}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{\mu}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k}$ is in the $k$-dimensional face $a_{s}^{k}$ of $a_{v}^{n-1}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1}$ is in the $(j+1)$-dimensional face $a_{r}^{j+1}$ of $a_{s}^{k}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j}$ is in the $j$-dimensional face $a_{q}^{j}$ of $a_{r}^{j+1}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{\mu}^{j-1}$ is in the $(j-1)$-dimensional face $a_{\mu}^{j-1}$ of $a_{q}^{j}$, $P_{l}^{0} P_{m}^{1} P_{n}^{2}$ is in the 2 -dimensional face $a_{n}^{2}$ of $a_{n}^{j-1}$
$P_{l}^{0} P_{m}^{1}$ is in the edge $a_{m}^{1}$ of $a_{n}^{2}$ and
$P_{l}^{0}$ is the vertex $a_{l}^{0}$ of $a_{m}^{1}$.

Since $P_{s}^{k}$ is an interior point of $S_{n}$, the ( $n-1$ )-dimensional face $a_{n}^{n-1}$ containing it, must have the centre of $S_{n}$ as a vertex and therefore by ( $a$ ) of the definition of a star, $a_{v}^{n-1}$ is common to two and only two $n$-dimensional simplexes $a_{w}^{n}$ and $a_{w^{\prime}}^{n}$ of $S_{n}$.

By the concluding remark of the previous paragraph the number of the simplexes $\bar{a}_{w}^{n}$ is finite. We require to prove that they satisfy conditions (a) and (b) of the definition of a simplex star.
(a) The (n-1)-dimensional faces of $\bar{a}_{w}^{n}$ of vertex $P_{s}^{k}$ are
(1) $P_{m}^{1} P_{n}^{2} \ldots, P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{n}^{n-1} P_{w}^{n}$
(2) $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} p_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{n-1} P_{w}^{n}$,

$$
(j=1,2, \ldots k-1, k+1, \ldots, n-1), \text { and }
$$

(3) $P_{l}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{n-1}$.
(1) Let $P_{l}^{0}$ and $P_{l^{\prime}}^{0}$ be the vertices of $a_{m}^{1}$. Then:

By definition (1) of Subdivision, $P_{l^{\prime}}^{0} P_{m}^{1}$ is an edge of $\bar{S}$, hence by definition (2) of subdivison, $P_{l^{\prime}}^{0} P_{m}^{1} P_{n}^{2}$ is a 2-dimensional simplex of $\bar{S}$. Applying definitions (3), (4), $\ldots,(n-1)$ and ( $n$ ) in succession we prove that $P_{l^{\prime}}^{0} P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{n-1} P_{w}^{n}$ is an $n$-dimensional simplex of $\overline{S .}$. Thus $P_{m}^{1} P_{n}^{2} \ldots P_{p}^{i-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{s}^{k} \ldots P_{v}^{n-1} P_{w}^{n}$ is common to two $n$-dimensional simplexes of $\bar{S}$. Any other $n$-dimensional simplex having the face $P_{m}^{1} P_{n}^{2} \ldots P_{w}^{n}$ must be of the form $P_{l^{\prime \prime}}^{0} P_{m}^{1} \ldots P_{w}^{n}$ and by definition (1) of the regular subdivision, $P_{l}^{0} P_{m}^{1}$ and $P_{l^{\prime}}^{0} P_{m}^{1}$ are the only edges of $\bar{S}$ of the form $P_{l^{\prime \prime}}^{0} P_{m}^{1}$ incident with $P_{n}^{1}$. Therefore $l^{\prime \prime}$ must be $l$ or $l^{\prime}$. Thus

$$
P_{m}^{1} P_{n}^{2} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} P_{s}^{k} P_{v}^{n-1} P_{w}^{n}
$$

is incident with two and only two $n$-dimensional simplexes of $\bar{S}$.
(2) The ( $j-1$ )-dimensional face $a_{p}^{j-1}$ is incident with two $j$-dimensional faces $a_{q}^{j}$ and $a_{q^{\prime}}^{j}$ of $a_{r}^{j+1}$. Therefore by definition ( $j$ ) of regular subdivision there are two $j$-dimensional simplexes $P_{l}^{0} \ldots P_{p}^{j-1} P_{q}^{j}$ and $P_{l}^{0} \ldots P_{p}^{j-1} P_{q^{\prime}}^{j}$ of $\bar{S}$ and by applying successively the definitions $(j),(j+1), \ldots,(n)$ of regular subdivision we obtain two simplexes $P_{l}^{0} \ldots P_{p}^{j-1} P_{q}^{j} P_{r}^{j+1} \ldots P_{w}^{n}$ and $P_{l}^{0} \ldots P_{p}^{j-1} P_{q^{\prime}}^{j} P_{r}^{j+1} \ldots P_{w}^{n}$ of $\bar{S}$ having $P_{l}^{0} \ldots P_{p}^{j-1} P_{r}^{j+1} \ldots P_{v v}^{n}$ as common ( $n-1$ )-dimensional face. Any other $n$-dimensional simplex having this face must be of the form :
$P_{l}^{0} \ldots P_{p}^{j-1} P_{q^{\prime \prime}}^{j} P_{r}^{j+1} \ldots P_{w}^{n}$, where by detinition $(j+1)$ of regular subdivision $a_{q^{\prime \prime}}^{j}$ is a $j$-dimensional face of $a_{r}^{j+1}$ incident with $a_{p}^{j-1}$, that is, $a_{q^{\prime \prime}}^{j}$ is either $a_{q}^{j}$ or $a_{q^{\prime}}^{j}$ and thus $P_{q^{\prime \prime}}^{j}$ is either $P_{q}^{j}$ or $P_{q^{\prime}}^{j}$. Thus $P_{l}^{0} \ldots P_{p}^{j-1} P_{r}^{j+1} \ldots P_{w}^{n}$ is an ( $n-1$ )-dimensional face of two and only two $n$-dimensional simplexes of $\bar{S}$.
(3) The ( $n-1$ )-dimensional face $a_{n}^{n-1}$ being common to two and only two $n$-dimensional simplexes $a_{w}^{n}$ and $a_{w^{\prime}}^{n}$ of $S_{n}$, it follows from definition ( $n$ ) of regular subdivision that the ( $n-1$ )-dimensional face $P_{l}^{0} P_{m}^{1} \ldots P_{v}^{n-1}$ of $\bar{S}$ is common to two and only two simplexes $P_{l}^{0} P_{m}^{1} \ldots P_{v}^{n-1} P_{v}^{n}$ and $P_{l}^{0} P_{m}^{1} \ldots P_{v}^{n-1} P_{w^{\prime}}^{n}$ of $\bar{S}$. Thus the simplexes of $\bar{S}$ of vertex $P_{s}^{k}$ satisfy condition ( $a$ ) of the definition of a star.
(b) Consider first the simplexes of $\bar{S}$ in $a_{w}^{n}$.

By definition (1) of regular subdivision any two edges of the subdivision of $a_{w}^{n}$ have either no point or a vertex in common. Hence by definition (2) any two 2-dimensional faces of the subdivision of $a_{w}^{n}$ have either no point or one vertex or one edge in common. Hence by definitions (3), (4), .., ( $n-1$ ) any two ( $n-1$ ). dimensional faces of the subdivision of $a_{w}^{\prime \prime}$ have either no point or one $p$-dimensional face in common, $(0 \leqslant p \leqslant n-2)$. Finally by definition ( $n$ ), any two $n$-dimensional simplexes of vertex $P_{w}^{n}$ of the subdivision of $a_{v}^{n}$ have one $p$-dimensional face in common, $(0 \leqslant p \leqslant n-1)$.

Consider now two $n$-dimensional simplexes $\bar{a}_{1}^{n}$ and $\bar{a}_{2}^{n}$ of $\bar{S}$ in the simpleses $a_{1}^{n}$ and $a_{2}^{n}$ of $S_{n}$. Then if $a_{1}^{n}$ and $a_{2}^{n}$ have no common point, $\bar{a}_{1}^{n}$ and $\bar{a}_{2}^{n}$ have no common point. If $a_{1}^{n}$ and $a_{2}^{n}$ have in common a $p$-dimensional face, $(0 \leqslant p \leqslant n-1)$, then by definition ( $n$ ), $\bar{a}_{1}^{n}$ and $\bar{a}_{2}^{n}$ have either no point or a $q$-dimensional face in common, $(0 \leqslant q \leqslant p)$ that is $(0 \leqslant q \leqslant p \leqslant n-1)$.

Thus any two $n$-dimensional simplexes of $\bar{S}$ have either no point or a $p$-dimensional face in common, $(0 \leqslant p \leqslant n-1)$ and in particular any two $n$-dimensional simplexes of $\bar{S}$ of vertex $P_{s}^{k}$ have either no point other than $P_{s}^{k}$ or a $p$-dimensional face, $(1 \leqslant p \leqslant n-1)$, in common.

Thus the simplexes $\bar{a}_{w}^{n}$ of vertex $P_{s}^{k}$ constitute a simplex star of centre $P_{s}^{k}$.

Theorem II. In $R_{n}$, any $n$-dimensional simples star of centre $A_{\text {. contains }}$ an $n$-dimensional spherical region of centre $A_{0}$.

The proof falls into two parts:
(1) If the theorem is true for $n=(p-1)$, it is true for $n=p$.
(2) The theorem is true for $n=1$.
(1) We assume then that in $R_{p-1}$, any ( $p-1$ )-dimensional simplex star of centre $P_{n}^{k}$ contains a ( $\mu-1$ )-dimensional spherical region of centre $P_{n}^{k}$. Consider in $R_{p}$, a $p$-dimensional star $S_{p}$ of centre $A_{0}$ and let $U\left(A_{0}\right)$ be a $p$-dimensional spherical neighbourhood of centre $A_{0}$, and radius $r$, where $r$ is less than the distance of $A_{0}$ from any point of the boundary of $S_{\mu}$. Let $P_{1}$ be any point of $U\left(A_{0}\right)$ in the simplex $a^{p}$ of $S_{p}$, and $P_{z}$ any point of $U\left(A_{0}\right)$ not in $a^{p}$ and not in the line $P_{1} A_{0}$. We require to prove that $P$, is in $S_{p}$.

Let $a_{l}^{i}, a_{m}^{j}, \ldots, a_{n}^{k},(i, j, \ldots, k \leqslant p-1)$, be the set of all simplexes, finite in number each of which contains one and only one point of the segment $P_{1} P_{1}$. Let $P_{1} P_{\text {, intersect }} a_{l}^{i}, a_{m}^{j}, \ldots, a_{n}^{k}$ in the points $P_{l}^{i}, P_{m}^{j}, \ldots, P_{n}^{k}$ respectively and let $P_{n}^{k}$ be the nearest of these points to $P_{2}$. (Assume $P_{n}^{k}$ to be different from $P_{2}$, for if $P_{n}^{k}=P_{3}$, then $P$, is in $\left.S_{p}\right)$. Since $U\left(A_{0}\right)$ contains no boundary points of $S_{p}$ the simplex $a_{n}^{k}$ containing $P_{n}^{c c}$ must be of the form $A_{0} A_{1} \ldots A_{k}$. Let $a_{n}^{k}=A_{0} A_{1} \ldots A_{k}$ be a $k$-dimensional tace of the simplex $A_{0} \ldots A_{k} \ldots A_{p}$ of $S_{p}$ and let $A_{1}^{\prime}, A_{2}^{\prime}, \ldots, A_{p-1}^{\prime}$ be points of $A_{0} A_{1}, A_{0} A_{2}, \ldots, A_{0} A_{p-1}$ respectively such that the simplex $A_{1}^{\prime} A_{2}^{\prime} \ldots A_{k}^{\prime}$ contains $P_{n}^{k}$ but such that the $R_{p-2}$ determined by $A_{1}^{\prime}, A_{2}^{\prime}, \ldots, A_{p-1}^{\prime}$, does not contain $P_{z}$. Then the $R_{p-1}$ determined by $A_{1}^{\prime}, A_{2}^{\prime}, \ldots, A_{d-1}^{\prime}, P$, contains the segment $P_{n}^{k} P_{2}$ and intersects $A_{0} A_{1}$ in one point $A_{1}^{\prime}$ only, so that $A_{0}$, and $A_{1}$ are on opposite sides of $R_{p-1}$ in $R_{p}$.

Consider now the intersection of $R_{p-1}$ and any $p$-dimensional simplex $A_{0} A_{1} A_{s_{2}} \ldots A_{s_{p}}$ of $S_{p}$ of edge $A_{0} A_{1}$. Then $R_{p-1}$ intersects one of the edges $A_{0} A_{s_{i}}, A_{s_{i}} A_{1}$ in a point $A_{s_{i}}$. Thus $R_{p-1}$ intersects the simplex $A_{0} A_{1} A_{s_{3}} \ldots A_{s_{p}}$ in a ( $p-1$ )-dimensional simplex $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p}}^{\prime}$ of vertex $A_{1}^{\prime}$. The set of such simplexes as $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p}}^{\prime}$ form a $(p-1)$ dimensional star $S_{p-1}^{\prime}$ of centre $A_{1}^{\prime}$ in $R_{p-1}$, for they are finite in number and satisfy the conditions (a) and (b) in the definition of a star. Thus:
(a) Because $S_{p}$ is a simplex star of centre $A_{0}$, the ( $p-1$ )-dimensional face $A_{0} A_{1} A_{s_{2}} \ldots A_{s_{p-1}}$ is common to two and only two
$p$-dimensional simplexes $A_{0} A_{1} A_{s_{2}} \ldots A_{s p-1} A_{s_{q}}$ and $A_{0} A_{1} A_{s_{2}} \ldots$ $A_{s_{p-1}} A_{s_{p}}$ and thus the ( $p-2$ )-dimensional face $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p-1}}^{\prime}$ is common to two and only two ( $p-1$ )-dimensional simplexes $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p-1}}^{\prime} A_{s_{p}}^{\prime}$ and $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p-1}}^{\prime} A_{s_{q}}^{\prime}$. Thus the simplexes $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p}}^{\prime}$ satisfy condition (a).
(b) Any two simplexes of $S_{p}$ of edge $A_{0} A_{1}$ have in common either no point other than the edge $A_{0} A_{1}$, or one $k$-dimensional face, $(k=2,3, \ldots, p-1)$. Therefore any two of the ( $p-1$ )-dimensional simplexes $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p}}^{\prime}$ have in common either no point other than $A_{1}^{\prime}$, or one $k$-dimensional face, $(k=1,2, \ldots, p-2)$, for if $A_{0} A_{1} A_{s_{2}} \ldots A_{s_{k}}$ is common to two simplexes of $S_{p}$, then $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{k}}^{\prime}$ is common to the two corresponding simplexes' in $R_{p-1}$.

Thus, from (a) and (b) the simplexes $A_{1}^{\prime} A_{s_{2}}^{\prime} \ldots A_{s_{p}}^{\prime}$ form a $(p-1)$. dimensional star $S_{p-1}$ in $R_{p-1}$ of centre $A_{1}^{\prime}$, and we have seen that $P_{n}^{k}$ is in the simplex $A_{1}^{\prime} A_{2}^{\prime} \ldots A_{k}^{\prime}$ of $S_{p-1}$. Therefore by Theorem I, $P_{n}^{k}$ is the centre of a $(p-1)$-dimensional star $S_{p-1}^{\prime}$ in $S_{p-1}$. Therefore by hypothesis, $S_{p-1}^{\prime}$ being in $R_{p-1}$, there is a ( $p-1$ ). dimensional spherical neigbourhood $U\left(P_{n}^{k}\right)$ of centre $P_{n}^{k}$ in $S_{p-1}^{\prime}$.

If $P_{2}$ be in $U\left(P_{n}^{k}\right)$ it is in $S_{\mu}$ and our theorem is proved. Consider the case when $P_{2}$ not in $U\left(P_{n}^{k}\right)$. Since $P_{n}^{k} P_{2}$ and $U\left(P_{k}^{n}\right)$ are in $R_{p-1}$, the segment $P_{n}^{k} P$, intersects the boundary of $U\left(P_{n}^{k}\right)$ in a point $Q$ and the segment $P_{n}^{k} Q$ is in $U\left(P_{n}^{k}\right)$ and thus in $S_{p}$. Let $Q$ be in the simplex $a^{q}$ of $S_{p}$, and note that $P_{2} Q$ contains none of the points $P_{l}^{i}, P_{m}^{i}, \ldots, P_{n}^{k}$. Since $P_{2}$ is in the $R_{q}$ containing $a^{q}$, and $Q$ is in $a^{q}, P_{2}$ must be in $a^{q}$ for otherwise $P_{2} Q$ would intersect the boundary of $a^{q}$ in one point which is impossible (since $P_{2} Q$ contains none of the points $\left.P_{l}^{i}, P_{m}^{j}, \ldots, P_{n}^{k}\right)$.

Thus $P$, is in $S_{\rho}$. Therefore $U\left(A_{0}\right)$ is in $S_{\mu}$ and the Theorem II is true for $n=p$, if it is true for $n=(p-\mathbf{1})$.
(2) The Theorem is true for $n=1$, for a 1-dimensional star of centre $A_{0}$ in $R_{1}$, is a segment of $R_{1}$, and $A_{0}$ is an inner point of the segment.

Thus Theorem II is true for any finite $n$.
