Physics. - Line spectrum of samarium ion in crystals and its variation with the temperature. By Simon Freed and J. G. Harwell. (Communicated by Prof. W. J. de Haas.)
(Communicated at the meeting of September 24, 1932.)

The magnetic behaviour of $S m^{+++1}$ ) showed that there was an equilibrium distribution of the ions between different electronic configurations and as anticipated, the absorption spectra ${ }^{2}$ ) consisted of lines varying in their relative intensities with changing temperature. The present work was instituted with the view of obtaining quantitative data concerning the differences in energy between the various configurations. These differences have been looked upon as originating through the action of the electric fields about $S m+++$ in the lattice. They are a measure of their symmetry and intensity. Recently, Miss Amelia Frank 3) obtained rough agreement with the magnetic susceptibility at higher temperatures by taking into account the presence of the activated state ${ }^{6} H_{\tau_{/ 2}}$, presumably about $1000 \mathrm{~cm}^{-1}$ higher in energy than the basic state ${ }^{6} H_{3 / 2}$. The agreement is rather surprising since both the basic state, ${ }^{6} H_{5 / 2}$ and activated states, ${ }^{6} H_{7 / 2}$ are probably decomposed into sub-levels of wide separation by the electric fields of the lattice. The specific heat of $\mathrm{Sm}^{+++4}$ ) at low temperature has given a measure of these separations. It appeared that energy of about $160 \mathrm{~cm}^{-1}$ ( $450 \mathrm{cal} / \mathrm{mole}$ ) had to be supplied to activate a mole of $\mathrm{Sm}^{+++}$. Even greater intervals may have resulted in the decomposition of the ${ }^{6} \mathrm{H}_{5 / 2}$ term but they must be so great that relatively few ions exist in the upper level.

The present work is mainly concerned with the effect of the electric fields upon the state ${ }^{6} H_{5 / 2}$ that is, with levels which are sufficiently occupied at ordinary temperatures to have their presence recorded in the absorption spectrum. They are identified by the change in the relative intensity of the lines as the temperature changes, more especially by those instances when a line increases in intensity apparently at the expense of a neighbouring line. When this line is of higher frequency than the one whose intensity is decreasing, there is considerable probability that the lines arise at two levels slightly different in energy and end in a common energy level. And the recurrence of the same interval in different regions of the spectrum practically establishes the existence and separation of the lower energy levels.

[^0]The experimental method has been described 1) in another connection. A hydrogen discharge tube served as the source of the continuous radiation and the spectra extended from $4200 \AA$ to about $2200 \AA$. A Hilger spectrograph of the type $E 2$ was employed. The radiation was passed parallel to the optic axis of the hexagonal crystal ${ }^{2}$ ) $\mathrm{Sm}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{SO}_{4}\right)_{3} .9 \mathrm{H}_{2} \mathrm{O}$ which was about 0.5 mm . thick. For the purpose of lowering the temperature of the crystal, liquid hydrogen ( $20^{\circ} \mathrm{K}$ ), liquid nitrogen ( $77^{\circ} \mathrm{K}$ ), and liquid ethylene ( $169^{\circ} \mathrm{K}$ ) were used, all boiling at atmospheric pressure. The average absolute error in the measurement of the lines is about $5 \mathrm{~cm}^{-1}$. Some of the lines were faint or diffuse and there has been listed next to each line in the table, the number of times it was measured and the reproducibility of the measurement. The recorded intensities are visual estimates and should be trusted only as a measure of relative intensity within a restricted region of the spectrum and in spectra originating at the same temperature.

The groups of lines assigned to energy levels have undergone such changes in intensity that the increase or decrease in intensity of one line with respect to another could be told at a glance on an enlargement of the spectrogram.

For convenience, the groups have been numbered on the reproductions of the spectra. Below each diagram is given a list of the frequencies derived from the energy levels and these are compared with the observed frequencies for each group of lines. All the deviations are well within the errors of measurement. Groups $4,7,8$ and 10 under low dispersion appear as doublets having the same energy difference at each temperature. Under higher dispersion, each line is found to be doubled and with the data in hand it is impossible to prove rigorously whether the "fine-structure" energy level belongs to the basic term system or not. More data, we are informed, will be available soon in a more extensive paper by Spedding and Bear from Berkeley. If the "fine-structure" level is assigned to the basic multiplet, it becomes possible to include the quartet 5 and also the sextet 3 and 6 . This arrangement of levels has a considerable degree of probability and by its aid all the multiplets in which marked intensity changes occur can be interrelated.

Below is a typical example of an energy level pattern which the quartets $4,7,8$ and 10 accord with and also the basic separations which are valid for all of them. The intensities, too, agree with these assignments.

Some of the lines which one would normally expect from these levels were too faint to be measured. At higher temperatures, some of the lines were so diffuse that the average between two unresolved lines is given.

There can be no doubt concerning the existence of an interval of $60 \mathrm{~cm}^{-1}$ (at $20^{\circ} \mathrm{K}, 65 \mathrm{~cm}^{-1}$ at $77^{\circ} \mathrm{K}$, and $60 \mathrm{~cm}^{-1}$ at $169^{\circ} \mathrm{K}$ ) between

two energy levels in the basic multiplet. Also, there is little doubt but that this interval can be related to the influence of the electric fields of the lattice upon ${ }^{6} H_{5 / 2}$. It may be predicted at this point that a close study of

the specific heat measurements at low temperatures will confirm the existence of this interval.

Based upon the same pattern of levels as those given above, the quartet 5 will have the following basic intervals:
$60 \mathrm{~cm}^{-1}$ at $20^{\circ} \mathrm{K}, 54 \mathrm{~cm}^{-1}$ at $77^{\circ} \mathrm{K}$, and $43 \mathrm{~cm}^{-1}$ at $169^{\circ} \mathrm{K}$.

| Temp. <br> ${ }^{\circ} \mathrm{K}$ | Calc. Line <br> $\mathbf{c m}^{-1}$ | Observed Line <br> $\mathbf{c m}^{-1}$ | Deviation |
| :---: | :---: | :---: | :---: |
| 20 |  | $30,115 \pm 2$ (accepted) <br> $30,133 \pm ?$ <br> 77 | 30.130 |
| 30,070 | $30,071 \pm 2$ | $30,058 \pm 1$ | 3 |
| 169 | 30,067 | $30,121 \pm 2$ (accepted) | 1 |
|  | 30,075 | $30,067 \pm 1$ | 3 |
|  |  | $30,118 \pm 1$ | 0 |

Now, it is clear that if the $12 \mathrm{~cm}{ }^{-1}$ interval (the "fine-structure" interval) is inserted in the basic multiplet of $4,7,8,10$, the group 5 fits into the same scheme as groups $4,7,8,10$ and we shall see later the sextets 3 and 6 will also be associated with the same levels. As an example we shall give the energy le els of group 4 and 5 at $77^{\circ} \mathrm{K}$ employing the same basic multiplet for $\mathrm{bo}^{+}$

The fact that the "fine-structure" interval is of the same magnitude in all groups (with the possible exception of 8 ) is evidence for including it

$$
\text { Quartet } 4 \text { and basic interval of } 5
$$

$77^{\circ} \mathrm{K}$.

in the basic multiplet. Its inclusion results naturally in any attempt to superpose the levels of the groups for the purpose of obtaining all the components which $6 H_{5 / 2}$ has been split into. The total number can not exceed six. It must be stated again that more data are necessary for this purpose, especially spectra at the temperature of liquid helium.

Since the spectrum of $\mathrm{Sm}^{+++}$consists of rather isolated groups, one would expect the lines within a group to originate and end at neighbouring levels. The intensities justify this point of view as the components of greater frequency always become more intense as the temperature is reduced. The sextets 3 and 6 contain the same energy interval as the quartet 5 and the intensities of corresponding lines behave in the same way with regard to temperature. We shall therefore associate 3 and 6 with the same basic states as 5 . Below is the energy level pattern of 3 based upon that of 5 .

A is the "fine structure level" which can be inserted in the basic multiplet so that the interval $10 \mathrm{~cm}^{-1}$ (or $12 \mathrm{~cm}^{-1}$ ) would be produced there (See page 982).

| Temp. K | Calc. Line $\mathrm{cm}^{-1}$ | Obs. Line $\mathrm{cm}^{-1}$ | Deviation $\mathrm{cm}^{-1}$ |
| :---: | :---: | :---: | :---: |
| $20^{\circ}$ |  | $27,639 \pm 1$ (accepted) |  |
|  | 27,629 | 27,629 $\pm 1$ | 0 |
|  | 27,597 | $27.597 \pm 0$ | 0 |
|  | 27,579 | $27.585 \pm 6$ | 6 |
|  | 27.537 | $27,537 \pm 0$ | 0 |
|  | 27,469 | $27,469 \pm 1$ | 0 |
| $77^{\circ}$ |  | $27.637 \pm 1$ (accepted) |  |
|  | 27,595 | $27,595 \pm 2$ | 0 |
|  | 27,541 | $27,540 \pm 1$ | 1 |
|  | 27,478 | $27,478 \pm 1$ | 0 |
| $169^{\circ}$ |  | $27,639 \pm 0$ |  |
|  | 27,591 | $27.591 \pm 1$ | 0 |
|  | 27.548 | $27.549 \pm 0$ | 0 |
|  | 27,491 | $27.491 \pm 0$ | 0 |

The sextet 6 follows a similar pattern, its first interval being identical at each temperature with that of 3 but the over-all separation of the basic multiplet is slightly different. This difference can probably be ascribed to another "fine-structure" interval in the basic term system. The over-all separation of $170 \mathrm{~cm}^{-1}$ agrees with the interval evaluated from the specific heat measurements ${ }^{1}$ ) ${ }^{2}$ ).

The lines which have been studied here because of the variation in their intensities constitute about one half the prominent lines of the spectrum.

A part of this experimental work was done by one of us (S. F.) during his stay in the laboratory of Professor de Haas Leyden, Holland while he was a fellow of the John Simon Guggenheim Memorial Foundation. He wishes to express his gratitude to Professor de HaAs for the generous hospitality of his laboratory.

## Summary.

The absorption spectra of $S m^{+++}$in the hexagonal crystal $\mathrm{Sm}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{SO}_{4}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ were taken parallel to the optic axis at $20^{\circ} \mathrm{K}$, $77^{\circ} \mathrm{K}$, and $169^{\circ} \mathrm{K}$. Absorption lines are listed in the region of the spectrum between $4200 \AA$ and $2200 \AA$.

This paper is principally concerned with the various electronic configurations in the basic multiplet, especially as they result from the inter-action of $\mathrm{Sm}^{+++}$and the electric fields of the lattice. In consequence, all the lines whose relative intensities vary with the temperature have been studied in terms of energy level diagrams.

Physics. - The Calibration of a Pressure Balance in Absolute Units. (31 ${ }^{\text {st }}$ Communication of the Van der Waals Fund). By A. Michels. (Communicated by Prof. J. D. van der Waals Jr.). (Communicated at the meeting of September 24, 1932.)

Introduction. For the measurement of pressure in absolute units, as soon as the pressure is greater than some atmospheres, the only method that need be considered is that using a mercury column. This method, however, involves considerable difficulties when the pressures to be measured become appreciable. A few examples are known of high pressure mercury manometers such as those of Amagat in a mine-shaft at Verpilleux near St. Etienne, and of Cailletet in the Eifel Tower, with which it was possible to measure up to about 400 atm . In the same group can be placed the so-called "gebroken manometer" designed by Kamerlingh Onnes, which is still in use for measurements up to 120 atm . We are unaware of any direct measurements with a mercury column besides these.

Of the secondary gauges in use the most suitable for accurate measurement is the pressure balance which also allows measurements to be made at much higher pressures. For the most accurate work it should, however, be calibrated directly. Many types of this apparatus are known (Amagat, Wiebe, Stückrath, Wagner, Lange, Holborn, Bridgman and others) all of which are designed on the same principle: a piston is ground to fit as well as possible in a cylinder; the unknown hydrostatic pressure is applied under the piston and the force is measured necessary to keep the piston in equilibrium. The pressure can then be calculated from

$$
P=\frac{K}{0}
$$

where $K$ is the force applied and 0 the area of the piston. By giving the piston a rotatory or to and fro motion the friction can be kept low.

[^1]:    ${ }^{1}$ ) J. E. Ahlberg and S. Freed, Phys. Rev. 39, 540 (1932).
    ${ }^{2}$ ) Dr. Spedding has kindly called my attention to some unpublished spectra of $\mathrm{Sm}_{2}\left(\mathrm{SO}_{4}\right)_{3} 8 \mathrm{H}_{2} \mathrm{O}$ which he and Mr . BEAR have taken. It appears that the interval of about $165 \mathrm{~cm}^{-1}$ in this salt corresponds to the $60 \mathrm{~cm}^{-1}$ interval recorded here for the ethylsulfate and hence the interval $170 \mathrm{~cm}^{-1}$ found in the ethylsulfate is not to be identified with the interval found in the specific heat measurements.
